Abstract

We study the discrete symmetries (P, C and T) on the kinematical level within the extended Poincaré Group. On the basis of the Silagadze research, we investigate the question of the definitions of the discrete symmetry operators both on the classical level, and in the secondary-quantization scheme. We study the physical content within several bases: light-front formulation, helicity basis, angular momentum basis, and so on, on several practical examples. The conclusion is that we have ambiguities in the definitions of the corresponding operators P, C; T, which lead to different physical consequences.
In his paper of 1992 Silagadze claimed: “It is shown that the usual situation when boson and its antiparticle have the same internal parity, while, fermion and its antiparticle have opposite particles, assumes a kind of locality of the theory. In general, when a quantum-mechanical parity operator is defined by means of the group extension technique, the reversed situation is also possible”, Ref. [1]. Then, Ahluwalia et al proposed [5] the Bargmann-Wightman-Wigner-type quantum field theory, where, as they claimed, boson and antiboson have opposite intrinsic parities (see also [6]). Actually, this type of theories has been first proposed by Gelfand and Tsetlin (1956), Ref. [7]. In fact, it is based on the two-dimensional representation of the inversion group. They indicated applicability of this theory to the description of the set of $K$-mesons and possible relations to the Lee-Yang paper. The (anti)commutativity of the discrete symmetry operations has also been investigated by Foldy and Nigam [8], who claimed that it is related to the eigenvalues of the charge operator. The relations of
the Gelfand-Tsetlin construct to the representations of the anti-de Sitter $SO(3, 2)$ group and the general relativity theory have also been discussed in subsequent papers of Sokolik. E. Wigner [9] presented related results at the Istanbul School on Theoretical Physics in 1962. Later, Fushchich et al discussed corresponding wave equations. Actually, the theory presented by Ahluwalia, Goldman and Johnson is the Dirac-like generalization of the Weinberg $2(2J + 1)$-theory for the spin 1. The equations have also been presented in the Sankaranarayanan and Good paper of 1965, Ref. [10]. In [11] the theory in the $(\frac{1}{2}, 0) \oplus (0, \frac{1}{2})$ representation based on the chiral helicity 4-eigenspinors was proposed. The corresponding equations have been obtained, e.g., in [3]. However, later we found the papers by Ziino and Barut [12] and the Markov papers [13], which also have connections with the subject under consideration. However, the question of definitions of the discrete symmetries operators raised by Silagadze, has not been clarified in detail. Explicit examples are presented below.
Helicity Basis and Parity.

The 4-spinors have been studied well when the basis has been chosen in such a way that they are eigenstates of the $\hat{S}_3$ operator:

\begin{align*}
u_{\frac{1}{2},\frac{1}{2}} &= N^+_{\frac{1}{2}} \begin{pmatrix} 1 \\ 0 \\ 1 \\ 0 \end{pmatrix}, \quad u_{\frac{1}{2},\frac{-1}{2}} = N^{+}_{-\frac{1}{2}} \begin{pmatrix} 0 \\ 1 \\ 0 \\ 1 \end{pmatrix}, \\
\nu_{\frac{1}{2},\frac{1}{2}} &= N^-_{\frac{1}{2}} \begin{pmatrix} 1 \\ 0 \\ -1 \\ 0 \end{pmatrix}, \quad \nu_{\frac{1}{2},\frac{-1}{2}} = N^{-}_{-\frac{1}{2}} \begin{pmatrix} 0 \\ 1 \\ 0 \\ -1 \end{pmatrix}.
\end{align*}

(1)

(2)

And, oppositely, the helicity basis case has not been studied almost at all (see, however, Refs. [14, 15]). Let me remind that the boosted 4-spinors $\Psi(p) = \text{column}(\phi_R(p) \pm \phi_L(p))$ in the 'common-used' basis are the parity eigenstates with the eigenvalues of $\pm 1$. 
In the helicity spin basis the 2-eigenspinors of the helicity operator [16]

\[
\frac{1}{2} \sigma \cdot \hat{p} = \frac{1}{2} \begin{pmatrix} \cos \theta & \sin \theta e^{-i\phi} \\ \sin \theta e^{i\phi} & -\cos \theta \end{pmatrix},
\]

(3)

\(\theta, \phi\) are the angles of the spherical coordinate system, can be defined as follows [16, 17]:

\[
\phi_{\frac{1}{2} \uparrow} \sim \begin{pmatrix} \cos \frac{\theta}{2} e^{-i\phi/2} \\ \sin \frac{\theta}{2} e^{i\phi/2} \end{pmatrix}, \quad \phi_{\frac{1}{2} \downarrow} \sim \begin{pmatrix} \sin \frac{\theta}{2} e^{-i\phi/2} \\ -\cos \frac{\theta}{2} e^{i\phi/2} \end{pmatrix},
\]

(4)

for \(h = \pm 1/2 = \uparrow \downarrow\) eigenvalues, respectively. We start from the Klein-Gordon equation, generalized for describing the spin-1/2 particles (i.e., two degrees of freedom), \(c = \hbar = 1\):

\[
(E + \sigma \cdot p)(E - \sigma \cdot p)\phi = m^2 \phi.
\]

(5)

It can be re-written in the form of the system of two first-order equations for 2-spinors as in the Sakurai book. At the same time,
we observe that they may be chosen as the eigenstates of the helicity operator:

\[(E - (\sigma \cdot p))\phi^\uparrow = (E - p)\phi^\uparrow = m\chi^\uparrow, \quad (6)\]
\[(E + (\sigma \cdot p))\chi^\uparrow = (E + p)\chi^\uparrow = m\phi^\uparrow, \quad (7)\]

\[(E - (\sigma \cdot p))\phi^\downarrow = (E + p)\phi^\downarrow = m\chi^\downarrow, \quad (8)\]
\[(E + (\sigma \cdot p))\chi^\downarrow = (E - p)\chi^\downarrow = m\phi^\downarrow. \quad (9)\]

If the \(\phi\) spinors are defined by the equation (4) then we can
construct the corresponding $u^-$ and $v^-$ 4-spinors\(^1\)

\[
u^+ = N^+\left(\frac{\phi^+}{E-p}\right) = \frac{1}{\sqrt{2}}\left(\frac{\sqrt{E+p}}{m}\phi^+\right)
\frac{\sqrt{m}}{E+p}\phi^+\right)
\]

\[
u^- = N^-\left(-\frac{\phi^-}{E+p}\right) = \frac{1}{\sqrt{2}}\left(-\frac{\sqrt{E+p}}{m}\phi^-\right)
= \frac{1}{\sqrt{2}}\left(-\frac{\sqrt{m}}{E+p}\phi^-\right)
\]

where the normalization to the unit ($\pm 1$) was used. One can prove...
that the matrix $P = \gamma^0 = \begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix}$ can be used in the parity operator as in the original Dirac basis. Indeed, the 4-spinors (11,13) satisfy the Dirac equation in the spinorial (Weyl) representation of the $\gamma$-matrices. Hence, the parity-transformed function $\Psi'(t, -x) = P\Psi(t, x)$ must satisfy 
\[
[i\gamma^\mu \partial'_\mu - m]\Psi'(t, -x) = 0 \quad \text{with} \quad \partial'_\mu = (\partial/\partial t, -\nabla_i).
\]
This is possible when $P^{-1}\gamma^0 P = \gamma^0$ and $P^{-1}\gamma^i P = -\gamma^i$. The P-matrix above satisfies these requirements, as in the textbook case [18].

Next, it is easy to prove that one can form the projection operators

\begin{align*}
P_+ &= + \sum_h u_h(p)\bar{u}_h(p) = \frac{p_\mu \gamma^\mu + m}{2m}, \\
P_- &= - \sum_h v_h(p)\bar{v}_h(p) = \frac{m - p_\mu \gamma^\mu}{2m},
\end{align*}

with the properties $P_+ + P_- = 1$ and $P_+^2 = P_+$. This permits us
to expand the 4-spinors defined in the basis (2) in linear superpositions of the helicity basis 4-spinors and to find corresponding coefficients of the expansion:

\[ u_\sigma(p) = A_{\sigma h} u_h(p) + B_{\sigma h} v_h(p), \quad v_\sigma(p) = C_{\sigma h} u_h(p) + D_{\sigma h} v_h(p). \]  

(16)

Multiplying the above equations by \( \bar{u}_h' \), \( \bar{v}_h' \) and using the normalization conditions, we obtain \( A_{\sigma h} = D_{\sigma h} = \bar{u}_h u_\sigma \), \( B_{\sigma h} = C_{\sigma h} = -\bar{v}_h u_\sigma \). Thus, the transformation matrix from the common-used basis to the helicity basis is

\[ \begin{pmatrix} u_\sigma \\ v_\sigma \end{pmatrix} = \mathcal{U} \begin{pmatrix} u_h \\ v_h \end{pmatrix}, \quad \mathcal{U} = \begin{pmatrix} A & B \\ B & A \end{pmatrix} \]  

(17)

Neither \( A \) nor \( B \) are unitary:

\[ A = (a_{++} + a_{+-})(\sigma_\mu a^\mu) + (-a_{--} + a_{-+})(\sigma_\mu a^\mu)\sigma_3, \]  

(18)

\[ B = (-a_{++} + a_{+-})(\sigma_\mu a^\mu) + (a_{--} + a_{-+})(\sigma_\mu a^\mu)\sigma_3. \]  

(19)
where
\[
a^0 = -i \cos(\theta/2) \sin(\phi/2) \in \Im m, \quad a^1 = \sin(\theta/2) \cos(\phi/2) \in \Re e, \\
a^2 = \sin(\theta/2) \sin(\phi/2) \in \Re e, \quad a^3 = \cos(\theta/2) \cos(\phi/2) \in \Re e,
\]
and
\[
a_{++} = \frac{\sqrt{(E + m)(E + p)}}{2\sqrt{2m}}, \quad a_{+-} = \frac{\sqrt{(E + m)(E - p)}}{2\sqrt{2m}}, \\
a_{--} = \frac{\sqrt{(E - m)(E + p)}}{2\sqrt{2m}}, \quad a_{-+} = \frac{\sqrt{(E - m)(E - p)}}{2\sqrt{2m}}.
\]
However, \(A^\dagger A + B^\dagger B = I\), so the matrix \(U\) is unitary. Please note that this matrix acts on the spin indices \((\sigma, h)\), and not on the spinorial indices; it is \(4 \times 4\) matrix.

We now investigate the properties of the helicity-basis 4-spinors with respect to the discrete symmetry operations \(P, C\) and \(T\). It is expected that \(h \rightarrow -h\) under parity, as Berestetskïi, Lifshitz and
Pitaevskii claimed [19]. Indeed, if $x \rightarrow -x$, then the vector $p \rightarrow -p$, but the axial vector $S \rightarrow S$, that implies the above statement. The helicity 2-eigenspinors transform $\phi_{\uparrow\downarrow} \Rightarrow -i\phi_{\downarrow\uparrow}$ with respect to $p \rightarrow -p$, Ref. [17]. Hence,

$$Pu_{\uparrow}(-p) = -iu_{\downarrow}(p), \quad Pu_{\downarrow}(-p) = -iu_{\uparrow}(p),$$

$$Pv_{\uparrow}(-p) = +iv_{\downarrow}(p), \quad Pv_{\downarrow}(-p) = +iv_{\uparrow}(p).$$

(23) (24)

Thus, on the level of classical fields, we observe that the helicity 4-spinors transform to the 4-spinors of the opposite helicity.

Also,

$$Cu_{\uparrow}(p) = -v_{\downarrow}(p), \quad Cv_{\uparrow}(p) = +u_{\downarrow}(p),$$

$$Cu_{\downarrow}(p) = +v_{\uparrow}(p), \quad Cv_{\downarrow}(p) = -u_{\uparrow}(p).$$

(25) (26)

due to the properties of the Wigner operator $\Theta \phi_{\uparrow}^* = -\phi_{\downarrow}$ and $\Theta \phi_{\downarrow}^* = +\phi_{\uparrow}$. Similar conclusions can be drawn in the Fock space.
We define the field operator as follows:

$$\psi(x^\mu) = \sum_h \int \frac{d^3 p}{(2\pi)^3} \sqrt{\frac{m}{2E}} [u_h(p)a_h(p)e^{-ip\cdot x^\mu} + v_h(p)b_h^\dagger(p)e^{+ip\cdot x^\mu}].$$

(27)

The commutation relations are assumed to be the standard ones [21, 22, 18, 20] (compare with Refs. [3, 11]). If one defines

$$U_P \psi(x^\mu) U_P^{-1} = \gamma^0 \psi(x'^\mu), \quad U_C \psi(x^\mu) U_C^{-1} = C \psi^\dagger(x^\mu)$$

and the anti-unitary operator of time reversal

$$(V_T \psi(x^\mu) V_T^{-1})^\dagger = T \psi^\dagger(x''^\mu),$$

then it is easy to obtain the corresponding transformations of the creation/annihilation operators:

$$U_P a_h(p) U_P^{-1} = -ia_{-h}(-p), \quad U_P b_h(p) U_P^{-1} = -ib_{-h}(-p),$$

(28)

$$U_C a_h(p) U_C^{-1} = (-1)^{\frac{1}{2}+h} b_{-h}(p), \quad U_C b_h(p) U_C^{-1} = (-1)^{\frac{1}{2}-h} a_{-h}(-p).$$

(29)
As a consequence, we obtain (provided that $U_P|0> = |0>$, $U_C|0> = |0>$)

$$U_P a_h^\dagger(p)|0> = U_P a_h^\dagger U_P^{-1}|0> = i a_{-h}^\dagger(-p)|0> = i| -p, -h >^+, \quad (30)$$

$$U_P b_h^\dagger(p)|0> = U_P b_h^\dagger U_P^{-1}|0> = i b_{-h}^\dagger(-p)|0> = i| -p, -h >^-, \quad (31)$$

and

$$U_C a_h^\dagger(p)|0> = U_C a_h^\dagger U_C^{-1}|0> = (-1)^{\frac{1}{2}+h} b_{-h}^\dagger(p)|0> =$$

$$(-1)^{\frac{1}{2}+h}| -p, -h >^- , \quad (32)$$

$$U_C b_h^\dagger(p)|0> = U_C b_h^\dagger U_C^{-1}|0> = (-1)^{\frac{1}{2}-h} a_{-h}^\dagger(p)|0> =$$

$$(-1)^{\frac{1}{2}-h}| -p, -h >^+ . \quad (33)$$
Finally, for the $CP$ operation one should obtain:

$$U_P U_C a_h^\dagger(p)|0\rangle = -U_C U_P a_h^\dagger(p)|0\rangle = (-1)^{\frac{1}{2} + h} U_P b_{-h}^\dagger(p)|0\rangle =$$

$$= i(-1)^{\frac{1}{2} + h} b_h^\dagger(-p)|0\rangle = i(-1)^{\frac{1}{2} + h} | -p, h >^- ,$$

$$U_P U_C b_h^\dagger(p)|0\rangle = -U_C U_P b_h^\dagger(p) = (-1)^{\frac{1}{2} - h} U_P a_{-h}^\dagger(p)|0\rangle =$$

$$= i(-1)^{\frac{1}{2} - h} a_h^\dagger(-p)|0\rangle = i(-1)^{\frac{1}{2} - h} | -p, h >^+ .$$

(34)

(35)

As in the classical case, the $P$ and $C$ operations anticommute in the $(\frac{1}{2}, 0) \oplus (0, \frac{1}{2})$ quantized case. This opposes to the theory based on 4-spinor eigenstates of chiral helicity (cf. [3]), where other definition was used, cf. [8] and below. Since the $V_T$ is an anti-unitary operator the problem must be solved after taking into account that in this case the $c$-numbers should be put outside the hermitian conjugation without complex conjugation:

$$[V_T h A V_{-1}^T]^\dagger = [h^* V_T A V_{-1}^T]^\dagger = h[V_T A^\dagger V_{-1}^T] .$$

(36)
After applying this definition we obtain:

\[ V_T a_h^\dagger(p) V_T^{-1} = + i (-1)^{\frac{1}{2} - h} a_h^\dagger(-p), \]  
\[ V_T b_h(p) V_T^{-1} = + i (-1)^{\frac{1}{2} - h} b_h(-p). \]  

Furthermore, we observed that the question of whether a particle and an antiparticle have the same or opposite parity properties depend on the phase factor in the following definition:

\[ U_P \psi(t, x) U_P^{-1} = e^{i\alpha} \gamma_0 \psi(t, -x). \]  

Indeed,

\[ U_P a_h(p) U_P^{-1} = - i e^{i\alpha} a_{-h}(-p), \]  
\[ U_P b_h^\dagger(p) U_P^{-1} = + i e^{i\alpha} b_{-h}^\dagger(-p). \]  

From this, if \( \alpha = \pi/2 \) we obtain opposite parity properties of
creation/annihilation operators for particles and anti-particles:

\[ U_P a_h(p) U_P^{-1} = +a_{-h}(-p), \]  
\( (42) \)

\[ U_P b_h(p) U_P^{-1} = -b_{-h}(-p). \]  
\( (43) \)

However, the difference with the Dirac case still preserves \( h \) transforms to \( -h \). We find somewhat similar situation with the question of constructing the neutrino field operator (cf. with the Goldhaber-Kayser creation phase factor).

Next, we find the explicit form of the parity operator \( U_P \) and prove that it commutes with the Hamiltonian operator. We prefer to use the method described in [20, §10.2-10.3]. It is based on the anzatz that \( U_P = \exp[i\alpha \hat{A}] \exp[i\hat{B}] \) with

\[ \hat{A} = \sum_s \int d^3p[a_{p,s}^\dagger a_{-p,s} + b_{p,s}^\dagger b_{-p,s}] \] and

\[ \hat{B} = \sum_s \int d^3p[\beta a_{p,s}^\dagger a_{p,s} + \gamma b_{p,s}^\dagger b_{p,s}] \].

On using the known operator identity

\[ e^{\hat{A}} \hat{B} e^{-\hat{A}} = \hat{B} + [\hat{A}, \hat{B}] + \frac{1}{2!} [\hat{A}, [\hat{A}, \hat{B}]] + \ldots \]  
\( (44) \)
and $[\hat{A}, \hat{B}\hat{C}]_- = [\hat{A}, \hat{B}]_+\hat{C} - \hat{B}[\hat{A}, \hat{C}]_+$ one can fix the parameters $\alpha, \beta, \gamma$ such that one satisfies the physical requirements that a Dirac particle and its anti-particle have opposite intrinsic parities. In our case, we need to satisfy the requirement that the operator should invert not only the sign of the momentum, but the sign of the helicity too. We may achieve this goal by the analogous postulate $U_P = e^{i\alpha\hat{A}}$ with

$$\hat{A} = \sum_h \int \frac{d^3p}{2E} [a^\dagger_h(p)a_{-h}(-p) + b^\dagger_h(p)b_{-h}(-p)].$$

(45)

By direct verification, the requirement is satisfied provided that $\alpha = \pi/2$. Cf. this parity operator with that given in [18, 20] for
Dirac fields:

\[ U_P = \exp \left[ i \frac{\pi}{2} \int d^3 p \sum_s \left( a(p, s)^\dagger a(\tilde{p}, s) + b(p, s)^\dagger b(\tilde{p}, s) - a(p, s)^\dagger a(p, s) + b(p, s)^\dagger b(p, s) \right) \right], \quad (10.69) \text{ of [20](46)} \]

By direct verification one can also come to the conclusion that our new \( U_P \) commutes with the Hamiltonian:

\[ \mathcal{H} = \int d^3 x \Theta^{00} = \int d^3 k \sum_h [a_h^\dagger(k) a_h(k) - b_h(k) b_h^\dagger(k)], \quad (47) \]

i.e.

\[ [U_P, \mathcal{H}]_-= 0. \quad (48) \]

Alternatively, we can try to choose another set of commutation relations [3, 11] for the set of bi-orthonormal states. The theory in the \( (\frac{1}{2}, 0) \oplus (0, \frac{1}{2}) \) representation based on the chiral helicity
4-eigenspinors was also proposed, see below. Next, a theory was presented which is based on a set of 6-component Weinberg-like equations in the $(1, 0) \oplus (0, 1)$ representation. The results are similar. The papers by Ziino and Barut [12] and the Markov papers [13] have also connections with the subject under consideration.
Chiral Helicity Construct and the Different Definition of the Charge Conjugation Operator on the Secondary Quantization Level.

In the chiral representation one can choose the spinorial basis (zero-momentum spinors) in the following way:

\[ \lambda^S_{\uparrow}(0) = \sqrt{\frac{m}{2}} \begin{pmatrix} 0 \\ i \\ 1 \\ 0 \end{pmatrix}, \lambda^S_{\downarrow}(0) = \sqrt{\frac{m}{2}} \begin{pmatrix} -i \\ 0 \\ 0 \\ 1 \end{pmatrix}, \]

\[ \lambda^A_{\uparrow}(0) = \sqrt{\frac{m}{2}} \begin{pmatrix} 0 \\ -i \\ 1 \\ 0 \end{pmatrix}, \lambda^A_{\downarrow}(0) = \sqrt{\frac{m}{2}} \begin{pmatrix} i \\ 0 \\ 0 \\ 1 \end{pmatrix}, \]
\[
\rho^S(S)^{(0)} = \sqrt{\frac{m}{2}} \begin{pmatrix} 1 \\ 0 \\ 0 \\ -i \end{pmatrix}, \quad \rho^S(S)^{(0)} = \sqrt{\frac{m}{2}} \begin{pmatrix} 0 \\ 1 \\ i \\ 0 \end{pmatrix},
\]
\[
\rho^A(A)^{(0)} = \sqrt{\frac{m}{2}} \begin{pmatrix} 1 \\ 0 \\ 0 \\ i \end{pmatrix}, \quad \rho^A(A)^{(0)} = \sqrt{\frac{m}{2}} \begin{pmatrix} 0 \\ 1 \\ -i \\ 0 \end{pmatrix}.
\]

The indices \(\uparrow \downarrow\) should be referred to the chiral helicity quantum number introduced in Ref. [11], \(\nu = -h\gamma_5\). Ahluwalia and Grumiller used the helicity basis for the 2nd-type 4-spinors. Using the boost the reader would immediately find the 4-spinors of the second kind \(\lambda^S(A)^{(p^\mu)}\) and \(\rho^S(A)^{(p^\mu)}\) in an arbitrary frame:
\[ \lambda^S_{\uparrow}(p^\mu) = \frac{1}{2\sqrt{E + m}} \begin{pmatrix} ip_l \\ i(p^- + m) \\ p^- + m \\ -p_r \end{pmatrix}, \lambda^S_{\downarrow}(p^\mu) = \frac{1}{2\sqrt{E + m}} \begin{pmatrix} -i(p^+ + m) \\ -ip_r \\ -p_l \\ (p^+ + m) \end{pmatrix}, \]

\[ \lambda^A_{\uparrow}(p^\mu) = \frac{1}{2\sqrt{E + m}} \begin{pmatrix} -ip_l \\ -i(p^- + m) \\ (p^- + m) \\ -p_r \end{pmatrix}, \lambda^A_{\downarrow}(p^\mu) = \frac{1}{2\sqrt{E + m}} \begin{pmatrix} i(p^+ + m) \\ ip_r \\ -p_l \\ (p^+ + m) \end{pmatrix}, \]
The helicity basis and parity.

Chiral helicity construct and the different definition of the charge conjugate operator on the secondary quantization level.

The conclusions.

Some of the 4-spinors are connected each other. The normalization

\[
\rho_{\uparrow}^{S}(p^\mu) = \frac{1}{2\sqrt{E + m}} \begin{pmatrix} p^+ + m & p_r \\ p_r & ip_l \\ -i(p^+ + m) \end{pmatrix}, \quad \rho_{\downarrow}^{S}(p^\mu) = \frac{1}{2\sqrt{E + m}} \begin{pmatrix} p_l \\ (p^- + m) \\ i(p^- + m) \end{pmatrix}, \quad \rho_{\uparrow}^{A}(p^\mu) = \frac{1}{2\sqrt{E + m}} \begin{pmatrix} p^+ + m & p_r \\ p_r & i(p^+ + m) \\ -i(p^- + m) \end{pmatrix}, \quad \rho_{\downarrow}^{A}(p^\mu) = \frac{1}{2\sqrt{E + m}} \begin{pmatrix} p_l \\ (p^- + m) \\ ip_r \end{pmatrix}.
\]
of the spinors $\lambda^{S,A}_{\uparrow\downarrow}(p^\mu)$ and $\rho^{S,A}_{\uparrow\downarrow}(p^\mu)$ are the following ones:

\begin{align}
\overline{\lambda}^{S}_{\uparrow}(p^\mu)\lambda^{S}_{\downarrow}(p^\mu) & = -im , \quad \overline{\lambda}^{S}_{\downarrow}(p^\mu)\lambda^{S}_{\uparrow}(p^\mu) = +im , \\
\overline{\lambda}^{A}_{\uparrow}(p^\mu)\lambda^{A}_{\downarrow}(p^\mu) & = +im , \quad \overline{\lambda}^{A}_{\downarrow}(p^\mu)\lambda^{A}_{\uparrow}(p^\mu) = -im , \\
\overline{\rho}^{S}_{\uparrow}(p^\mu)\rho^{S}_{\downarrow}(p^\mu) & = +im , \quad \overline{\rho}^{S}_{\downarrow}(p^\mu)\rho^{S}_{\uparrow}(p^\mu) = -im , \\
\overline{\rho}^{A}_{\uparrow}(p^\mu)\rho^{A}_{\downarrow}(p^\mu) & = -im , \quad \overline{\rho}^{A}_{\downarrow}(p^\mu)\rho^{A}_{\uparrow}(p^\mu) = +im .
\end{align}

All other conditions are equal to zero. Imposing that $\lambda^{S}(p^\mu)$ (and $\rho^{A}(p^\mu)$) answer for positive-frequency solutions; $\lambda^{A}(p^\mu)$ (and $\rho^{S}(p^\mu)$), for negative-frequency solutions, one can deduce the dynamical coordinate-space equations [3]:

\begin{align}
i\gamma^{\mu}\partial_{\mu}\lambda^{S}(x) - m\rho^{A}(x) & = 0 , \\
i\gamma^{\mu}\partial_{\mu}\rho^{A}(x) - m\lambda^{S}(x) & = 0 , \\
i\gamma^{\mu}\partial_{\mu}\lambda^{A}(x) + m\rho^{S}(x) & = 0 , \\
i\gamma^{\mu}\partial_{\mu}\rho^{S}(x) + m\lambda^{A}(x) & = 0 .
\end{align}
They can be written in the 8-component form. This is just another representation of the Dirac-like equation in the appropriate Clifford Algebra. One can also re-write the equations into the two-component form, the Feynman-Gell-Mann equations. In the Fock space operators of the charge conjugation and space inversions can be defined as above. We imply the bi-orthonormal system of the anticommutation relations. As a result we have the following properties of creation (annihilation) operators in the Fock space:

\[
U^{s}_{[1/2]} a^\dagger(p)(U^{s}_{[1/2]})^{-1} = -ia_{\downarrow}(-p), \quad U^{s}_{[1/2]} a_{\downarrow}(p)(U^{s}_{[1/2]})^{-1} = +ia^\dagger(-p),
\]

\[
U^{s}_{[1/2]} b^\dagger(p)(U^{s}_{[1/2]})^{-1} = +ib^\dagger_{\downarrow}(-p), \quad U^{s}_{[1/2]} b_{\downarrow}(p)(U^{s}_{[1/2]})^{-1} = -ib^\dagger_{\uparrow}(-p),
\]

that signifies that the states created by the operators \(a^\dagger(p)\) and \(b^\dagger(p)\) have different properties with respect to the space inversion operation, comparing with Dirac states (the case also regarded

Valeriy V. Dvoeglazov
P, C and T: Different Properties on the Kinematical Level
in [12]):

\[
\begin{align*}
U_{[1/2]}^s |p, \uparrow>^+ &= +i | -p, \downarrow>^+, U_{[1/2]}^s |p, \uparrow>^- = +i | -p, \downarrow>^-, \quad (65) \\
U_{[1/2]}^s |p, \downarrow>^+ &= -i | -p, \uparrow>^+, U_{[1/2]}^s |p, \downarrow>^- = -i | -p, \uparrow>^-.
\end{align*}
\]

For the charge conjugation operation in the Fock space we have two physically different possibilities. The first one, e.g.,

\[
\begin{align*}
U_c^{[1/2]} a_{\uparrow}(p) (U_c^{[1/2]})^{-1} &= +b_{\uparrow}(p), U_c^{[1/2]} a_{\downarrow}(p) (U_c^{[1/2]})^{-1} = +b_{\downarrow}(p), \\
U_c^{[1/2]} b_{\uparrow}(p) (U_c^{[1/2]})^{-1} &= -a_{\uparrow}(p), U_c^{[1/2]} b_{\downarrow}(p) (U_c^{[1/2]})^{-1} = -a_{\downarrow}(p),
\end{align*}
\]

in fact, has some similarities with the Dirac construct. The action...
of this operator on the physical states are

\[
U^c_{[1/2]} |p, \uparrow \rangle^+ = + |p, \uparrow \rangle^-, \quad U^c_{[1/2]} |p, \downarrow \rangle^+ = + |p, \downarrow \rangle^- \quad (69)
\]

\[
U^c_{[1/2]} |p, \uparrow \rangle^- = - |p, \uparrow \rangle^+, \quad U^c_{[1/2]} |p, \downarrow \rangle^- = - |p, \downarrow \rangle^+ \quad (70)
\]

But, one can also construct the charge conjugation operator in the Fock space which acts, e.g., in the following manner:

\[
\tilde{U}^c_{[1/2]} a^\dagger (p)(\tilde{U}^c_{[1/2]})^{-1} = - b^\dagger (p), \quad \tilde{U}^c_{[1/2]} a (p)(\tilde{U}^c_{[1/2]})^{-1} = - b (p), \quad (71)
\]

\[
\tilde{U}^c_{[1/2]} b^\dagger (p)(\tilde{U}^c_{[1/2]})^{-1} = + a^\dagger (p), \quad \tilde{U}^c_{[1/2]} b (p)(\tilde{U}^c_{[1/2]})^{-1} = + a (p), \quad (72)
\]

and, therefore,

\[
\tilde{U}^c_{[1/2]} |p, \uparrow \rangle^+ = - |p, \downarrow \rangle^-, \quad \tilde{U}^c_{[1/2]} |p, \downarrow \rangle^+ = - |p, \uparrow \rangle^- \quad (73)
\]

\[
\tilde{U}^c_{[1/2]} |p, \uparrow \rangle^- = + |p, \downarrow \rangle^+, \quad \tilde{U}^c_{[1/2]} |p, \downarrow \rangle^- = + |p, \uparrow \rangle^+ \quad (74)
\]
Next, by straightforward verification one can convince ourselves about correctness of the assertions made in [11b] (see also [8]) that it is possible a situation when the operators of the space inversion and charge conjugation commute each other in the Fock space. For instance,

\[
U^c_{[1/2]} U^s_{[1/2]} |p, \uparrow>^+ = +i U^c_{[1/2]} | -p, \downarrow>^+ = +i | -p, \downarrow> \qquad (75)
\]

\[
U^s_{[1/2]} U^c_{[1/2]} |p, \uparrow>^+ = U^s_{[1/2]} |p, \uparrow>^- = +i | -p, \downarrow>^- . \quad (76)
\]

The second choice of the charge conjugation operator answers for the case when the \( \tilde{U}^c_{[1/2]} \) and \( U^s_{[1/2]} \) operations anticommute:

\[
\tilde{U}^c_{[1/2]} U^s_{[1/2]} |p, \uparrow>^+ = +i \tilde{U}^c_{[1/2]} | -p, \downarrow>^+ = -i | -p, \uparrow> \qquad (77)
\]

\[
U^s_{[1/2]} \tilde{U}^c_{[1/2]} |p, \uparrow>^+ = -U^s_{[1/2]} |p, \downarrow>^- = +i | -p, \uparrow>^- . \quad (78)
\]

Finally, the time reversal \emph{anti-unitary} operator in the Fock space should be defined in such a way the formalism to be compatible
with the $CPT$ theorem. If we wish the Dirac states to transform as $V(T)|p, \pm 1/2 > = \pm | -p, \mp 1/2 >$ we have to choose (within a phase factor), Ref. [18]:

$$S(T) = \begin{pmatrix} \Theta[1/2] & 0 \\ 0 & \Theta[1/2] \end{pmatrix} \quad .$$

(79)

Thus, in the first relevant case we obtain for the $\Psi(x^\mu)$ field, composed of $\lambda^{S,A}$ or $\rho^{A,S}$ 4-spinors

$$V^T a^\dagger(p)(V^T)^{-1} = a^\dagger(-p), \quad V^T a^\dagger(p)(V^T)^{-1} = -a^\dagger(-p)$$

(80)

$$V^T b^\dagger(p)(V^T)^{-1} = b^\dagger(-p), \quad V^T b^\dagger(p)(V^T)^{-1} = -b^\dagger(-p),$$

(81)

that is not surprising.
The Conclusions.
Thus, we proceeded as in the textbooks and defined the parity matrix as $P = \gamma_0$, because the helicity 4-spinors satisfy the Dirac equation, and the 2nd-type $\lambda$-spinors satisfy the coupled Dirac equations. Nevertheless, the properties of the corresponding spinors appear to be different with respect to the parity both on the first and the second quantization level. The result is compatible with the statement made by Berestetskii, Lifshitz and Pitaevskii. We defined another charge conjugation operator in the Fock space, which also transforms the positive-energy 4-spinors to the negative-energy ones. In this case the operators $P$ and $C$ commute (instead of the anticommutation in the Dirac case), that is related to the eigenvalues of the charge operator, as in the Foldy and Nigam paper.
