

Production and Suppression of $X(3872)$

Content

The dependence of the production of the $X(3872)$ meson on the hadron multiplicity in pp collisions has been used as evidence against X being a charm-meson molecule. The argument is based in part on the incorrect assumption that the cross section for the breakup of X by scattering with comovers can be approximated by a geometric cross section inversely proportional to the binding energy of X . The breakup cross section should instead be approximated by the probability-weighted sum of the cross sections for the scattering of comoving pions from the charm-meson constituents of X , which is insensitive to the binding energy. A simple modification of the comover interaction model gives excellent fits to the data from the LHCb collaboration on the multiplicity dependence of the production of X and $\psi(2S)$, giving a range of compatible values for reaction rate of X and comovers.
