## 6.2.2 $K_v$ Method

Phong Nguyen (PhD thesis)  
GAP-2018-011

The  $K_v$  method reduces the reliance on some of the simplifying assumptions outlined in Section 6.2.1, providing a more reliable (on an individual pixel basis) conversion for the measured NSB variance into a photon flux. The following method was adapted from references [132–134].

Firstly, the variance scaling factor  $K_v$  is defined as follows

$$K_v = \frac{I_{ADC}}{\sigma_{ADC}^2} \quad (6.10)$$

## Calculating photon fluxes from background files (BG files record signal variances)

the complete analogue signal chain [132]. Using information provided by  $K_v$ , the photon flux is given by

$$\Phi_\gamma = \frac{[\sigma_{ADC}^2]^{NSB} \times K_v \times C_{FD}}{A \times \Delta t} \quad [\text{photons/m}^2/\text{deg}^2/\mu\text{s}] \quad (6.12)$$

where definitions of  $[\sigma_{ADC}^2]^{NSB}$ ,  $C_{FD}$ ,  $A$  and  $\Delta t$  were provided in Section 6.2.1.

- $C_{FD}$  is the calibration constant and can be thought of as the *inverse gain* of the pixel of interest (see Section 5.1).  $C_{FD}$  values are available through the FD Calibration database.
- $A$  is the pixel aperture =  $7.68 \text{ m}^2 \text{ deg}^2$  (the telescope aperture multiplied by the square of an FD pixel's angular size).
- $\Delta t$  is chosen to be 100 ns.

**$K_v$  is not explicitly stored in the monitoring database.**

## Calculating photon fluxes from background files (BG files record signal variances)

The software used to analyse the cal A data (and produce the relevant calibration parameters to be uploaded to the monitoring database) contains the following equation:

$$G = \frac{\sigma_{ADC}^2}{I_{ADC}} / F \times Sphe_{res} / 5 / range_{coeff} \quad (6.13)$$

where  $Sphe_{res}$  and  $range_{coeff}$  are predefined constants with values of 1.4 and 0.99893, respectively. By substituting in Equation 6.10, this can be rewritten as

$$G = \frac{1}{K_v} / F \times Sphe_{res} / 5 / Range_{coeff} \quad (6.14)$$

which can be rearranged to give

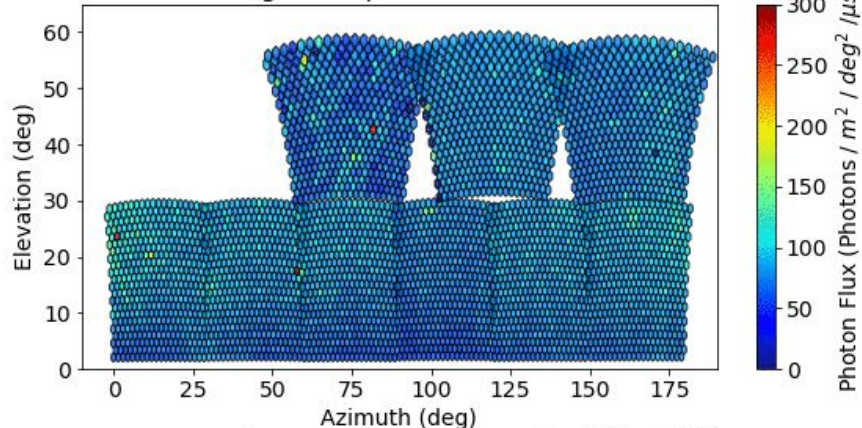

$$K_v = \frac{5}{G \times F \times Sphe_{res} \times range_{coeff}} \quad (6.15)$$

G is the PMT gain (ADC counts per photoelectron)  
F is the noise equivalent bandwidth (MHz)

**Kv is not explicitly stored in the monitoring database, but G and F are.**

# Conclusions

- BG files have been used to monitor the Heat/Coihueco relative energy scale with a precision of about 2% (in each HEAT mirror!) for the period from 2010 to 2018.
- We need to create a relative calibration DB for each HEAT mirror to account for the variability.

## Further applications of the BG files

- We have evaluated further applications of the BG files, such as:
  - Cloud detection,
  - Measuring the FD optical spot shape using bright stars.

We will report at the next Collaboration meeting.
