- 1 Introduction
- 2 Description of the analysis
- 3 Results
- 4 Summary

J/ψ meson

- The observation of the J/ψ meson marked the discovery of the charm quark, confirming the existence of a fourth quark flavor
- Studying this system helps us understand non perturbative QCD

- Quarkonium production in hadronic collisions has been the subject of many theoretical and experimental studies

$$\sigma(H) = \sum_n \hat{\sigma}(Q\bar{Q}[n]) \langle \mathcal{O}_n^H \rangle \quad (1)$$

- Measurement of long-distance matrix elements (LDME) present in non-perturbative hadronization processes from a theoretical framework to the description of quarkonium production using an effective NRQCD theory
- Additional data can help in improving the fits and determine more precisely the relative weights of the LDMEs

Quarkonia Production

$$\mathcal{L} \times \sigma(pp \rightarrow Q) \times \mathcal{B}(Q \rightarrow \mu^+ \mu^-) \times \epsilon \times \mathcal{A} = N$$

The product of the branching fraction of quarkonia to muon pairs, $\mathcal{B}(Q \rightarrow \mu^+ \mu^-)$, and the double-differential production cross section, $\frac{d^2\sigma}{dp_T dy}$, in bins of p_T and rapidity, y , is given by:

$$\frac{d^2\sigma(pp \rightarrow Q)}{dp_T dy} \times \mathcal{B}(Q \rightarrow \mu^+ \mu^-) = \frac{N(p_T, y)}{\mathcal{L} \Delta p_T \Delta y \epsilon(p_T, y) \mathcal{A}(p_T, y)}$$

donde:

- N : Number of prompt signal events in the bin
- \mathcal{L} : Integrated luminosity
- $\Delta p_T, \Delta y$: Bin widths
- $\epsilon(p_T, y)$: Reconstruction efficiency of the bin
- $\mathcal{A}(p_T, y)$: Acceptance of the bin

Acceptances and efficiencies

The acceptance for dimuon events in a given (p_T, y) range is defined as:

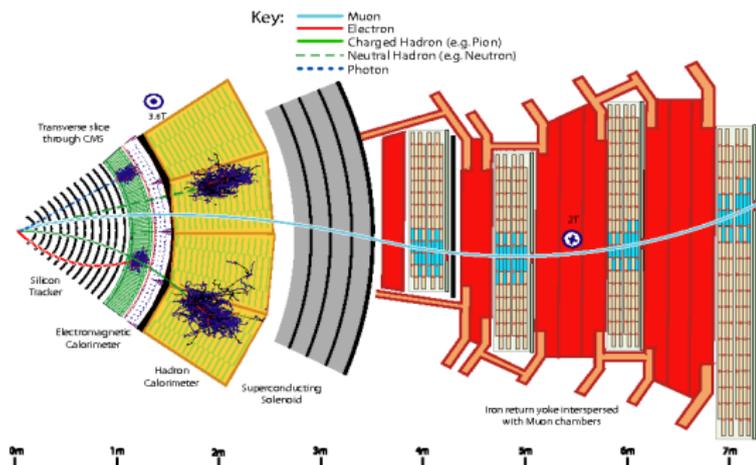

$$\mathcal{A}(p_T, y) = \frac{N_{kin}^{gen}(p_T, y)}{N^{gen}(p_T, y)}$$

where N_{kin}^{gen} is the number of event that pass the kinematic selection and N^{gen} is the total number of events generated.

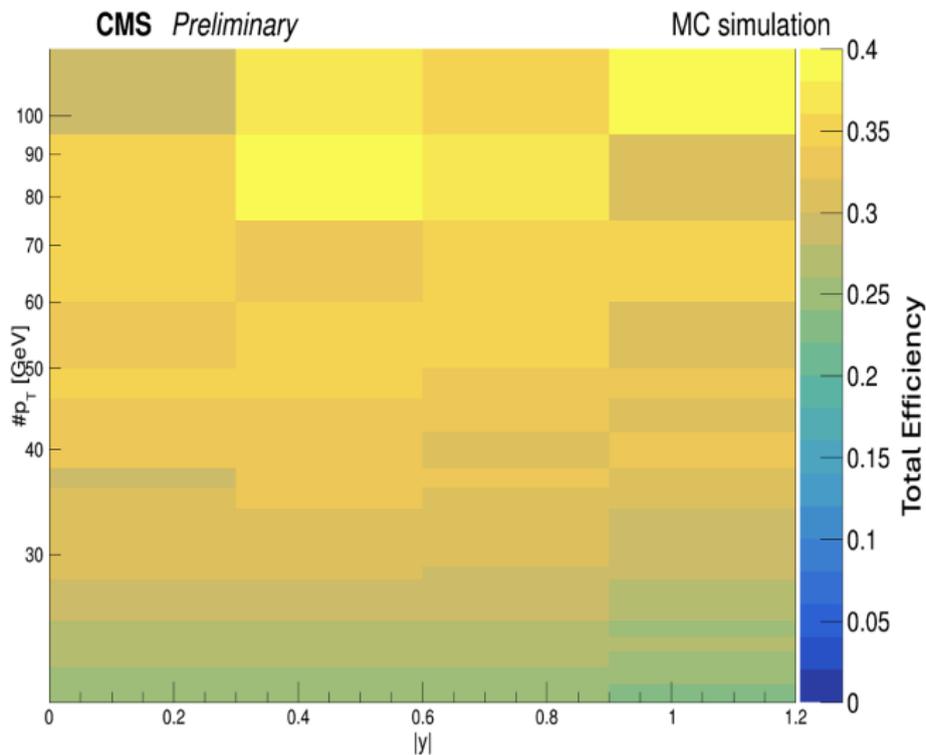

Efficiency is defined as:

$$\epsilon(p_T, y) = \frac{N^{full}(p_T, y)}{N^{RecoGen}(p_T, y)}$$

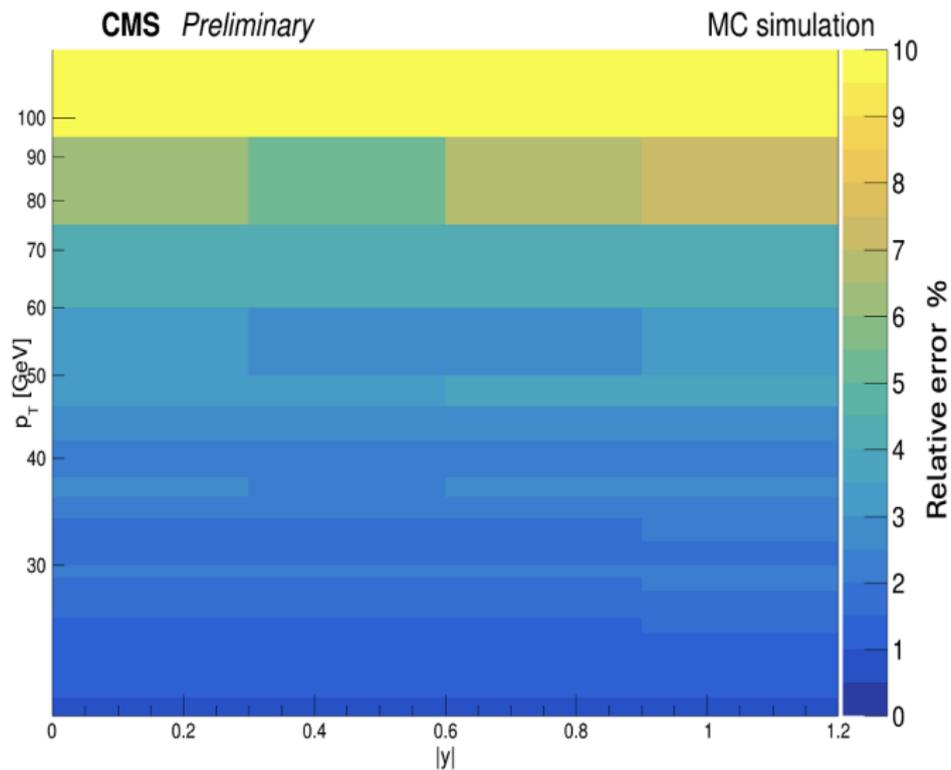

The ratio of events that were accepted, reconstructed and triggered to the events that were generated and accepted.

Total Efficiency

Relative error of the total efficiency

Determination of the yields

The prompt signal yields are obtained through an extended unbinned maximum-likelihood fit to the dimuon invariant mass and decay length distributions.

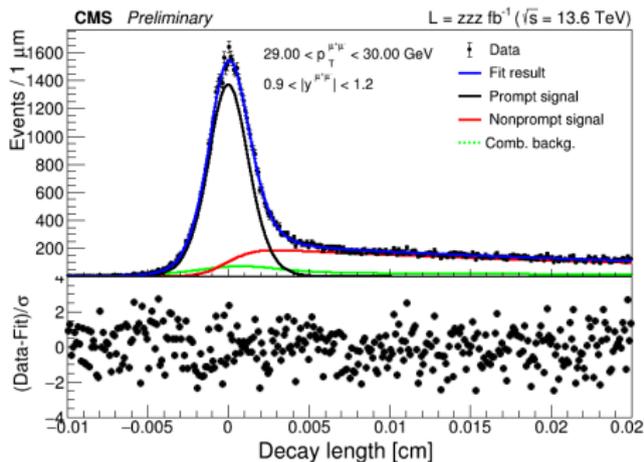

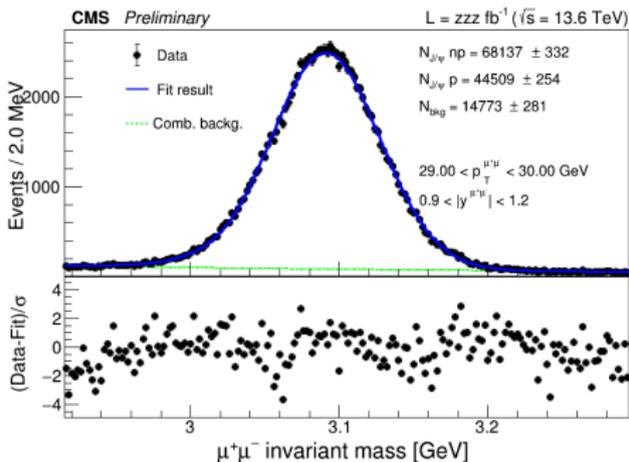

Mass Invariant Distribution

- Signal: a single sided Crystal Ball plus a Gaussian Function
- Background: Decreasing exponential function
- $\mathcal{F}(m_{\mu\mu}) = n_{NP} M_{Sig}(m_{\mu\mu}) + n_{PR} M_{Sig}(m_{\mu\mu}) + n_{Bkg} M_{Bkg}(m_{\mu\mu})$

Decay Length Distribution

- Prompt component (resolution): Two Gaussian Functions
- Non Prompt component: Exponential decay function convolved with the resolution
- Background: Two Gaussians plus an Exponential decay function convolved with the resolution
- $\mathcal{L}(ct, \sigma_i) = n_{NP} L_{NP}(ct, \sigma_{ct,i}) + n_{PR} L_{PR}(ct, \sigma_{ct,i}) + n_{Bkg} L_{Bkg}(ct, \sigma_{ct,i})$

Determination of the yields

Systematic Uncertainties

Uncertainties in the estimation of the yields are evaluated by changing the fixed/constrained parameters of the signal model and background models used in the maximum-likelihood fits.

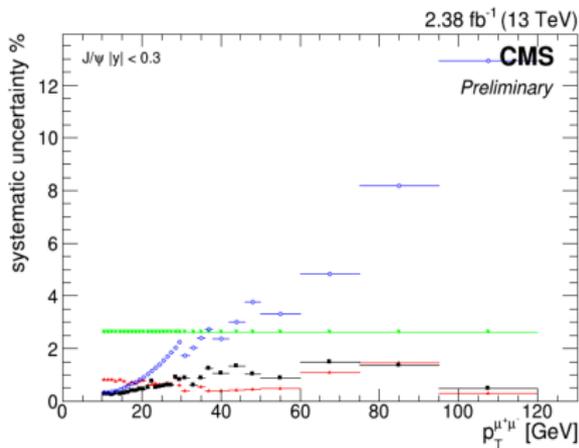

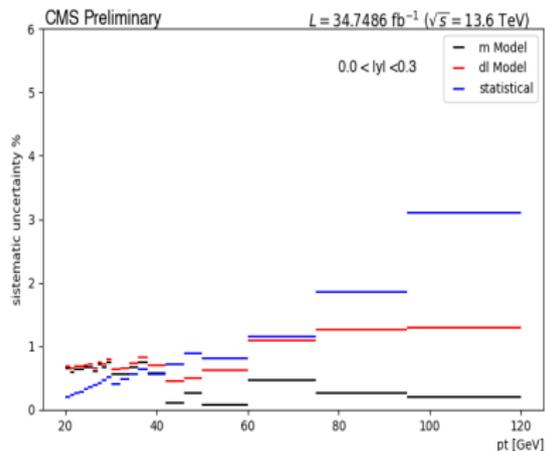

Mass Invariant Distribution

- μ which was fixed \rightarrow free parameter
- CB is modified in its fixed parameter $n \rightarrow n \pm 5\sigma$
- Bkg \rightarrow We changed to a linear shape

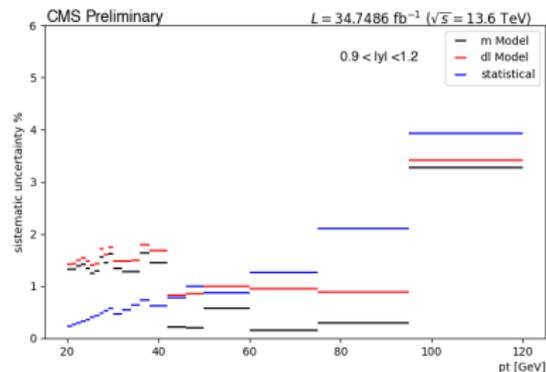

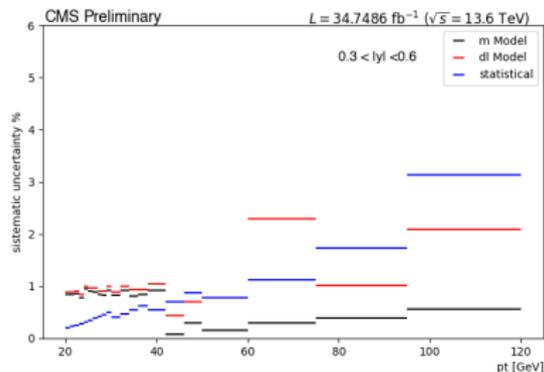

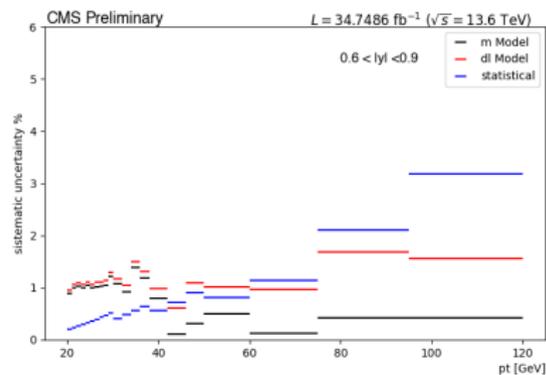

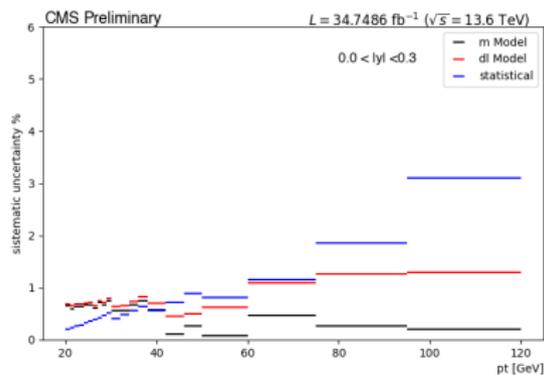

Decay Length Distribution

- The σ 's variables of the resolution function (which were constraint) are varied by ± 1 standard deviation to study the impact of imperfect modeling of the resolution function
- The lifetime of the non prompt signal component, due to real b hadrons, should not depend on the p_T or y . We tested this hypothesis fixing the λ parameter in the fit
- Bkg \rightarrow A two side exponential plus a negative exponential tail and a positive exponential tail

Systematic and Statistical Uncertainties

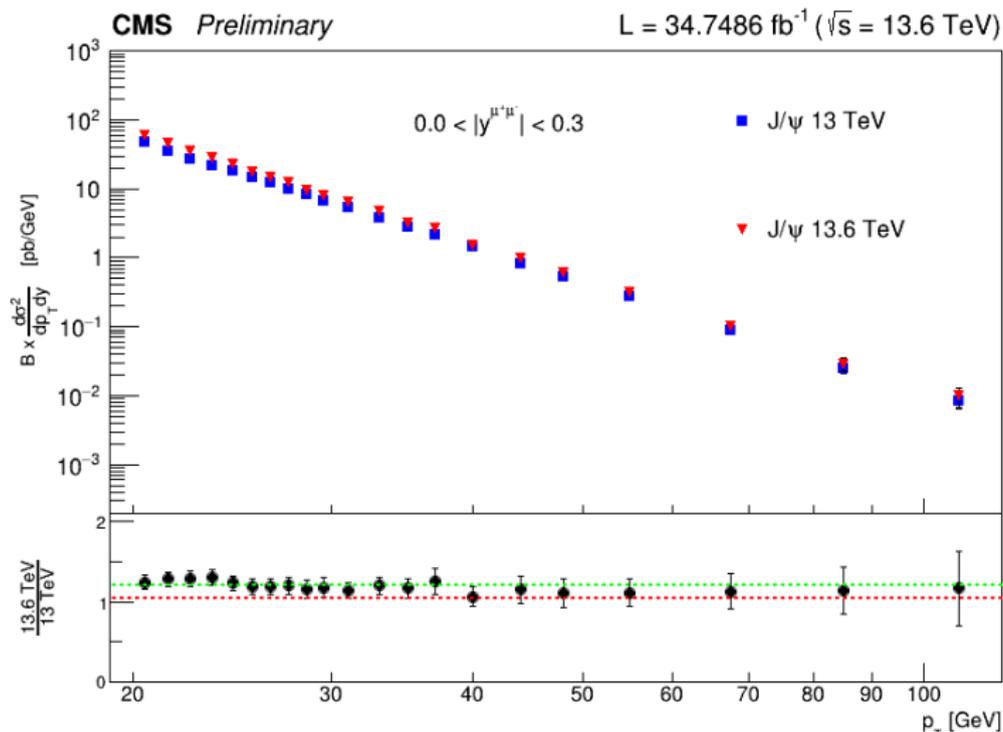

Systematic and Statistical Uncertainties

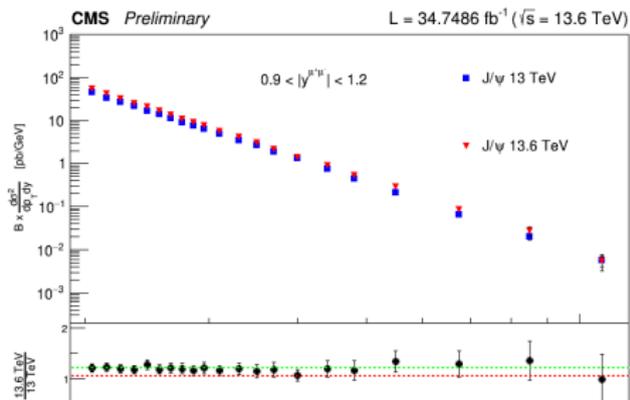

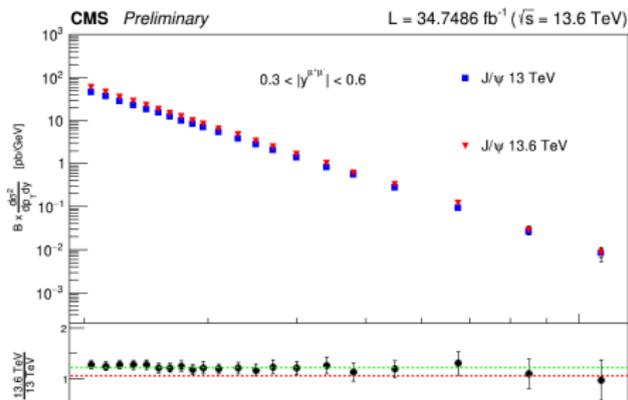

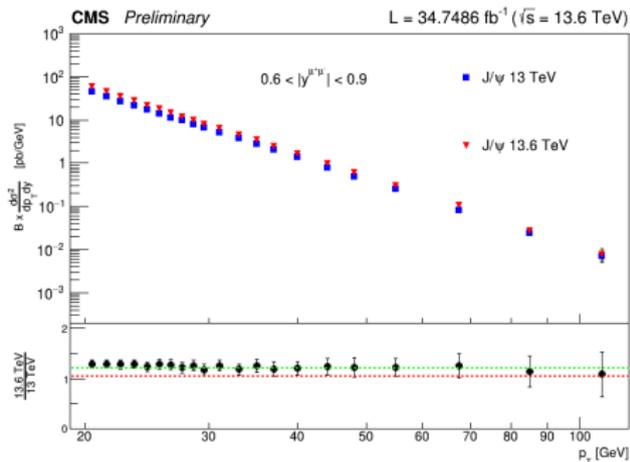

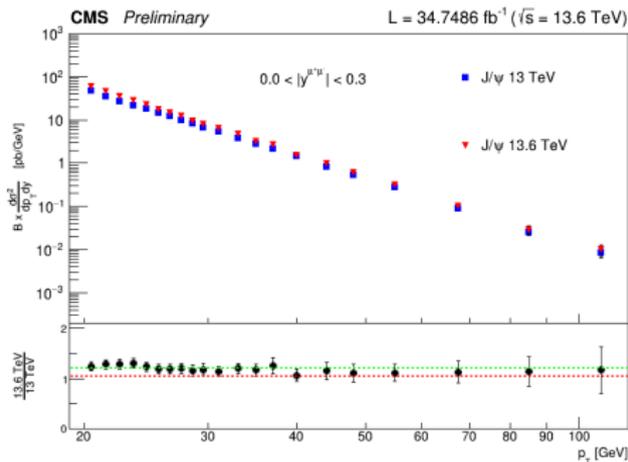

Preliminary results

Comparison between previous and current analysis

Preliminary results

- The double-differential production cross section of the J/ψ has been measured, using its dimuon decay mode, in pp collisions at $\sqrt{s} = 13.6$ TeV with the CMS detector at the LHC.
- The results obtained are in agreement with previous analyses at $\sqrt{s} = 13$ TeV
- The addition of new data has greatly reduced the statistical error

¡Thank you!

Prompt cross sections times branching ratios for the J/ψ

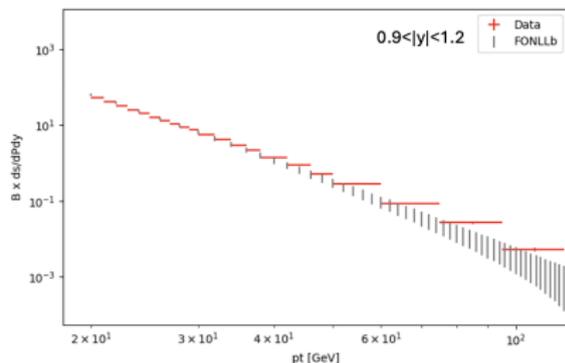

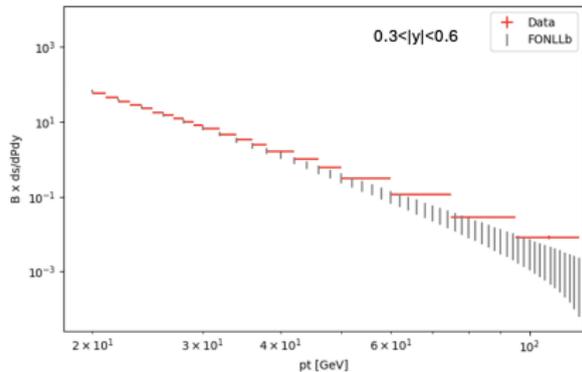

FONLL Approximation

$$\frac{d^2\sigma(pp \rightarrow J/\psi)}{dp_T dy} \cdot \mathcal{B}(J/\psi \rightarrow \mu^+\mu^-) =$$

$$\left[\frac{d^2\sigma(pp \rightarrow c\bar{c})}{dp_T dy} \cdot f(c\bar{c} \rightarrow J/\psi) \right] \cdot \mathcal{B}(J/\psi \rightarrow \mu^+\mu^-) -$$

$$\frac{d^2\sigma(pp \rightarrow b\bar{b} \rightarrow B)}{dp_T dy} \cdot f(c\bar{c} \rightarrow J/\psi) \cdot \mathcal{B}(J/\psi \rightarrow \mu^+\mu^-)$$

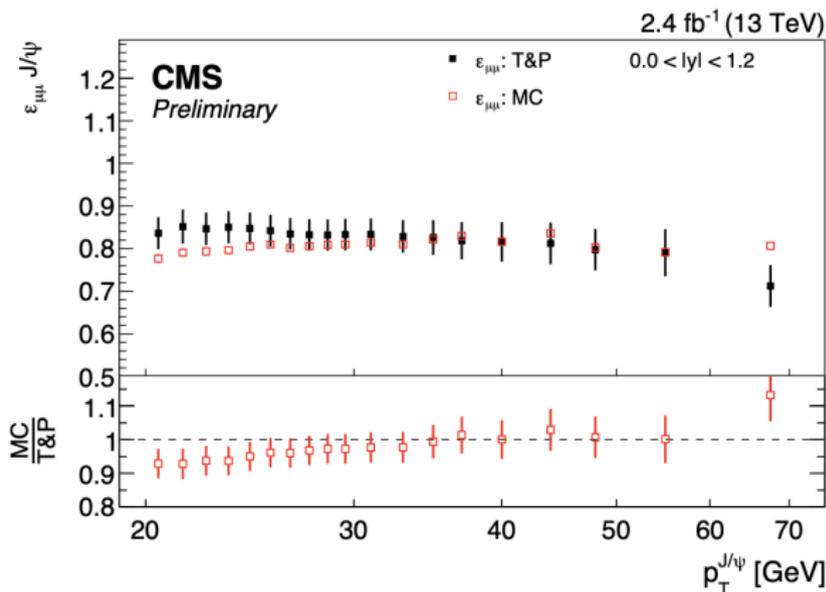

Prompt cross sections times branching ratios for the J/ψ

Efficiencies with Tag Probe Approach

Single-muon efficiencies are measured with a data-driven approach known as Tag and Probe (TnP). Total dimuon efficiencies are then obtained through the equation:

$$\epsilon_{\mu\mu}(pT, y) = \epsilon(pT_1, \eta_1)\epsilon(pT_2, \eta_2)\rho(pT, y)\epsilon_{tk}^2$$

$$\frac{d^2 N}{d \cos \theta d \phi} \propto 1 + \lambda_{\theta} \cos^2 \theta + \lambda_{\phi} \sin^2 \theta \cos(2\phi) + \lambda_{\theta\phi} \sin(2\theta) \cos \phi$$

Where θ, ϕ are the angles of the muons in a reference frame (usual, HX)

Reconstruction and Selection

Acceptance cuts

- $p_T(\mu_{1,2}) > 4\text{GeV}$, for $|\eta(\mu_{1,2})| < 0,3$

Tracker or global muons satisfied

- Tracker track matched with at least one muon segment (in any station) in both X and Y coordinates ($< 3\sigma$) (TMOneStationTight) and arbitrated
- Number of tracker layer with hits > 5 . This requirement guarantees a good p_T measurement, for which some minimal number of measurement points in the tracker is needed. Also suppresses muons from in-flight decays
- Number of pixel layers > 0 , to further suppress muons from in-flight decays
- High-purity track flag. This requirement rejects tracks of bad quality
- Loose transverse and longitudinal impact parameter cuts: $d_{xy} < 0,3\text{cm}$, $d_z < 20\text{cm}$ w.r.t. the primary vertex. This requirement implies (loose) compatibility with the PV (or beam spot)

Transverse momentum: 21 Bins

- 20-30 GeV, width = 1 GeV
- 30-38 GeV, width = 2 GeV
- 38-50 GeV, width = 4 GeV
- 50-60, 60-75, 75-95, 95-120 GeV

Rapidity: 4 Bins

- (0,0.3), (0.3,0.6), (0.6,0.9), (0.9,1.2)
