Status and performance of the ARGO-YBJ trigger system.

Friday, 6 July 2007 14:45 (0:00)

Abstract content

The ARGO-YBJ ground-based detector allows to investigate many issues in gamma-ray astronomy and cosmic ray physics spanning a large energy range by means of its ability to operate down to a few hundreds of GeV up to a few PeV. The apparatus consists of a single layer of about 2000 Resistive Plate Chambers (RPCs) for a total instrumented area of ~6700 m2. The whole detector has been fully equiped with final front-end, trigger and DAQ electronics and is in data taking since last February. The detection of small size showers is one of main tasks of the ARGO-YBJ experiment. The maximum trigger rate due to cosmic rays that the system can acquire is 15 KHz with a data transfer rate of about 16 MB/s. In this paper the design and performance of the trigger system will be described.
