A study of multiple interactions of high energy muons at the Baksan Underground Scintillation Telescope.

Abstract content

The paper studies the possibility of measuring a “prompt” muon signal by means of recording multiple interactions of muons. The main problem on data treatment is the reconstruction of the interactions in a muon group which accompanies usually a high energy muon. Results of data processing within the span of 4 years (live time = 22100 hours) are presented.
