The ultra-high energy cosmic ray spectrum and Fermi shock acceleration.

Wednesday, 4 July 2007 14:45 (0:00)

Abstract content

The energy spectrum of ultra-high energy cosmic rays (UHECR) is usually calculated for sources with identical properties. Assuming that all sources can accelerate UHECR protons to the same extremely high maximal energy $E_{\text{max}} > 10^{20}$ eV and have the steeply falling injection spectrum $1/E^{2.7}$, one can reproduce the measured cosmic ray flux above $E > 10^{18}$ eV. We show that relaxing the assumption of identical sources and using a power-law distribution of their maximal energy allows one to explain the observed UHECR spectrum with the injection $1/E^2$ predicted by Fermi shock acceleration. We study possible ways to distinguish between these two cases with future experiments.
