Some remarks about lateral distribution funtion of charged particles at energy above 10^17 eV.

Wednesday, 4 July 2007 14:45 (0:00)

Abstract content

The lateral distribution funtion (LDF) of charged particles is a basic characteristics of extensive air showers (EAS). It is necessary for determination of total number of particles at observation level and this number is used as an estima of primary energy. We consider the experimental LDF's obtained with MSU, Yakutsk and AGASA arrays. It should be noted that scintillator detectors of the AGASA and Yakutsk arrays detectors measure the energy deposit of shower particles at different distances from shower core whereas Geiger counters employed at the MSU array measure the number of charged particles directly. Experimental data are compared with calculations in the framework of the QGSJET model. It is shown that some discrepancy between various LDF's exists.
