Accelerators and Colliders

- The name of the game: access new Bosons and new Fermions by **colliding Fermions together**.
- Analyze collision dynamics as a 4-vector:

$$\Pi = [(E_1 + E_2), (\vec{p}_1 + \vec{p}_2)]$$

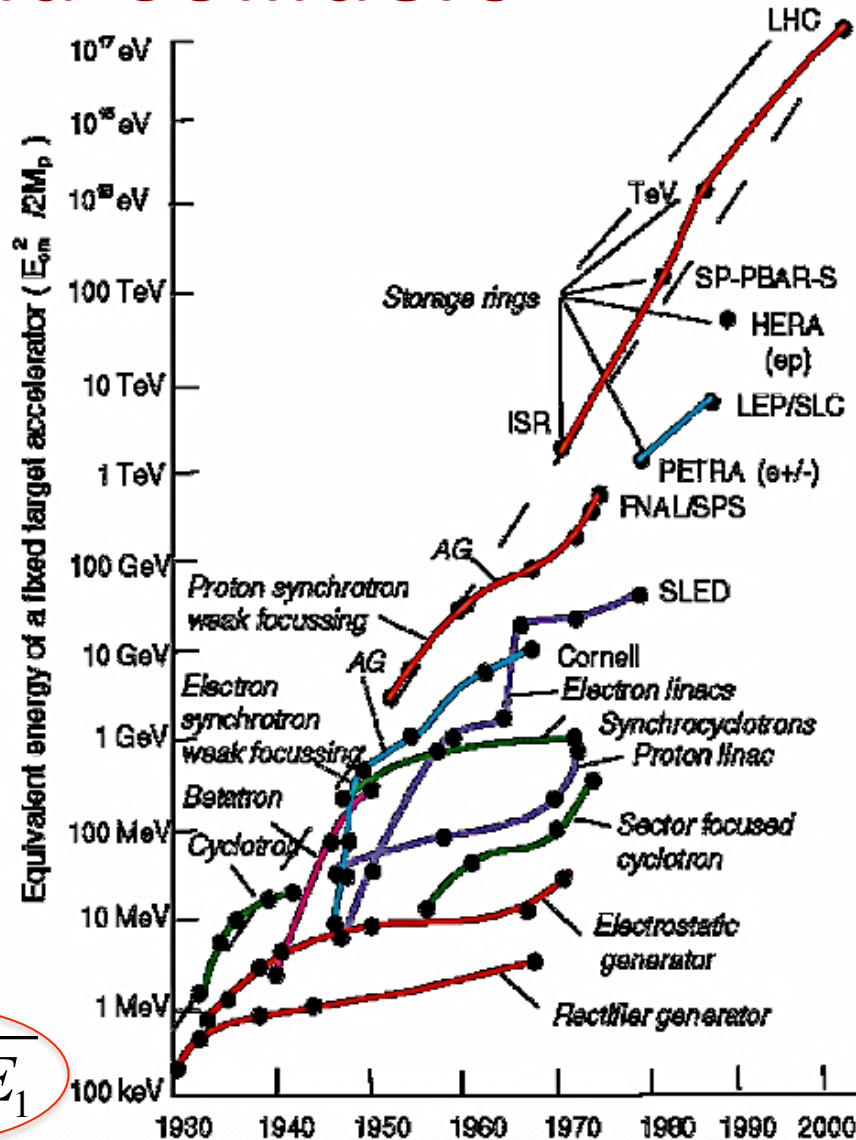

$$\Pi^2 = (E_1 + E_2)^2 - (\vec{p}_1 + \vec{p}_2)^2$$

- Two ways to do it:
 - ✦ Collide beam on target

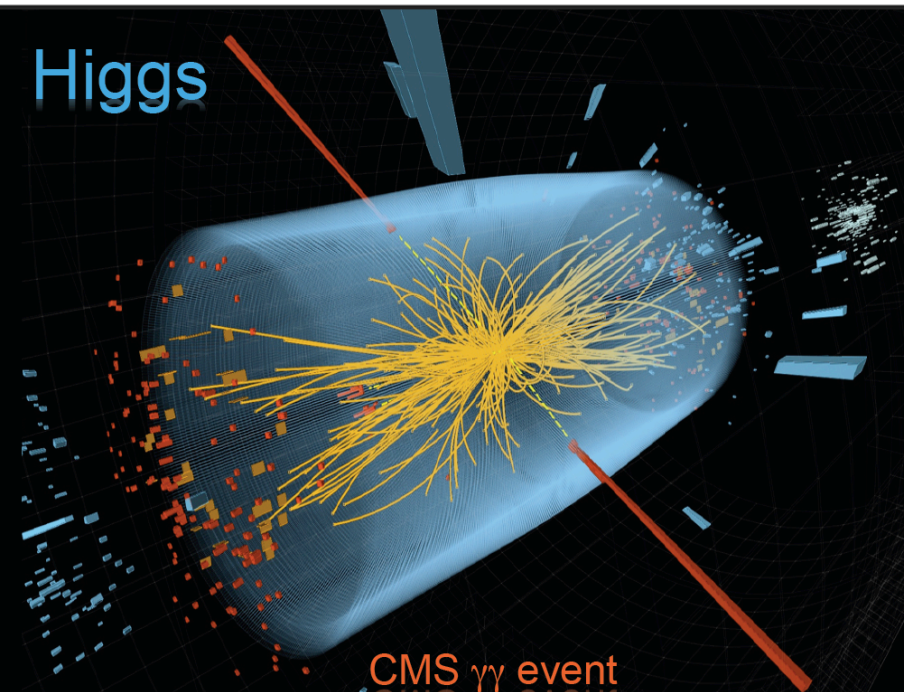

$$E_2 = m_2, \quad p_2 = 0, \quad \sqrt{\Pi^2} = \sqrt{2m_2 E_1}$$

- ✦ Collide beams head-on

$$E_1 = E_2 = E, \quad \vec{p}_1 = -\vec{p}_2 \cong E, \quad \sqrt{\Pi^2} = 2E$$

Present state of the art

LHC produces collisions at
Collision energy $\sqrt{s} = 13 \text{ TeV}$
Luminosity $\mathcal{L} = 10^{34} \text{ cm}^{-2}\text{s}^{-1}$

On July 4, 2012 the LHC experiments discovered the Higgs boson with mass $\mathcal{M} = 125 \text{ GeV}/c^2$

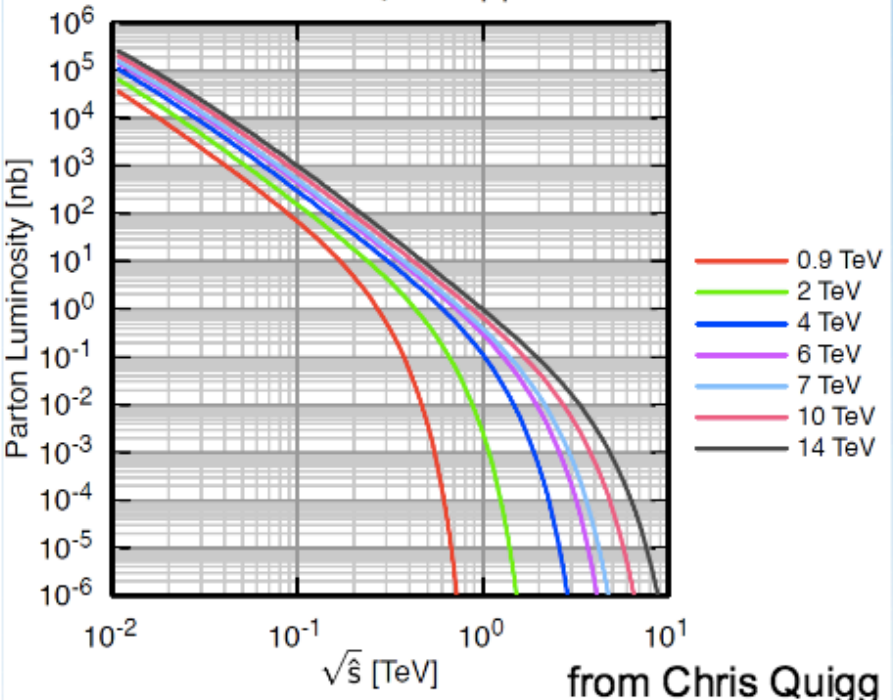

Parton Luminosity

CTEQ6L1: gg

CTEQ6L1: qq

from Chris Quigg

Example: $s^{1/2} = 14 \text{ TeV}$, $\hat{s}^{1/2} = 1 \text{ TeV}$

cross section: $\sigma \sim 0.01^2$ parton luminosity $\sim 0.1 \text{ pb}$ (if couplings ~ 0.01)

luminosity $L = 10 \text{ pb}^{-1} \rightarrow N_{\text{event}} = L \sigma = 1 \text{ event}$

CMS Preliminary

Need Maximum possible luminosity

Need Maximum possible collision energy

Accelerators: Linacs and Synchrotrons

- Linacs:

$\beta < 1$: drift tube linac

- Particle beam optics
- Beam cooling
- $\bar{p}p$ collider
- pp collider
- $\mu^+\mu^-$ collider

Bending and focusing beams

The physics of accelerators builds upon a common framework, in which three elements are arranged in sequence:

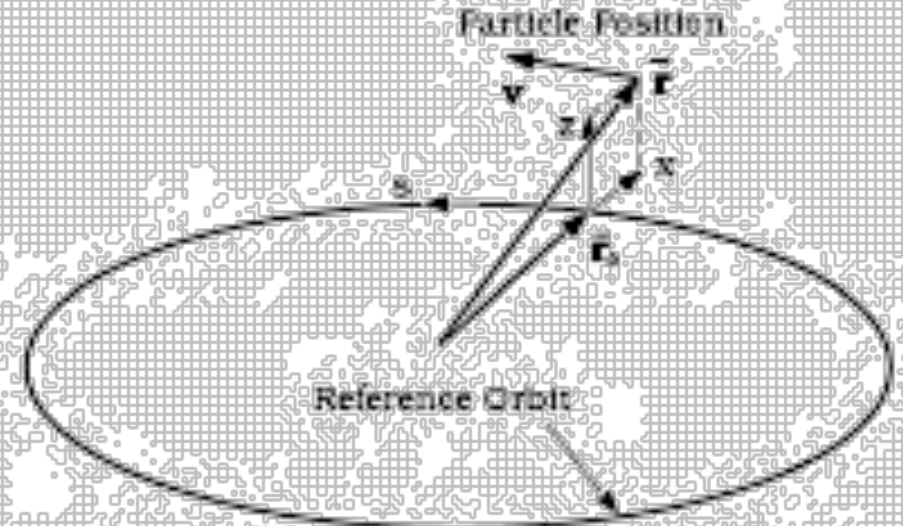

- dipole magnets to bend the bunches in a circular orbit (omitted for a linac);
- Quadrupole magnets to focus the bunches and confine them in transverse phase space;
- RF cavities to accelerate the bunches and confine them in bunches in longitudinal phase space.

$$\frac{d\vec{P}}{dt} = e(\vec{E} + \vec{v} \times \vec{B})$$

$$\vec{E} = -\nabla\Phi - \frac{\partial \vec{A}}{\partial t}, \quad \vec{B} = \nabla \times \vec{A}$$

$$H = e\Phi + c\sqrt{m^2c^2 + (\vec{P} - e\vec{A})^2}$$

$$\dot{x}_i = \frac{\partial H}{\partial P_i}, \quad \dot{P}_i = -\frac{\partial H}{\partial x_i} - e\dot{c}_i$$

Taylor series expansion

$$\phi = \sum_{n=1}^{\infty} \phi_n r^n \sin n\theta$$

Field in polar coordinates:

$$B_r = -\frac{\partial \phi}{\partial r}, \quad B_\theta = \frac{1}{r} \frac{\partial \phi}{\partial \theta}$$

$$B_r = \phi_n n r^{n-1} \sin n\theta, \quad B_\theta = \phi_n n r^{n-1} \cos n\theta$$

To get vertical field

$$\begin{aligned} B_z &= B_r \sin \theta + B_\theta \cos \theta \\ &= -\phi_n n r^{n-1} [\cos \theta \cos n\theta + \sin \theta \sin n\theta] \\ &= \phi_n n r^{n-1} \cos(n-1)\theta = \phi_n n x^{n-1} \quad (\text{when } y=0) \end{aligned}$$

Taylor series of multipoles

$$\begin{aligned} B_z &= \phi_0 + \phi_2 \cdot 2x + \phi_3 \cdot 3x^2 + \phi_4 \cdot 4x^3 + \dots \\ &= B_0 + \frac{1}{1!} \frac{\partial B_z}{\partial x} x + 2 \frac{\partial^2 B_z}{\partial x^2} x^2 + \frac{1}{3!} \frac{\partial^3 B_z}{\partial x^3} x^3 + \dots \end{aligned}$$

Dip. Quad Sext Octupole

Magnet types

◆ Dipoles bend the beam

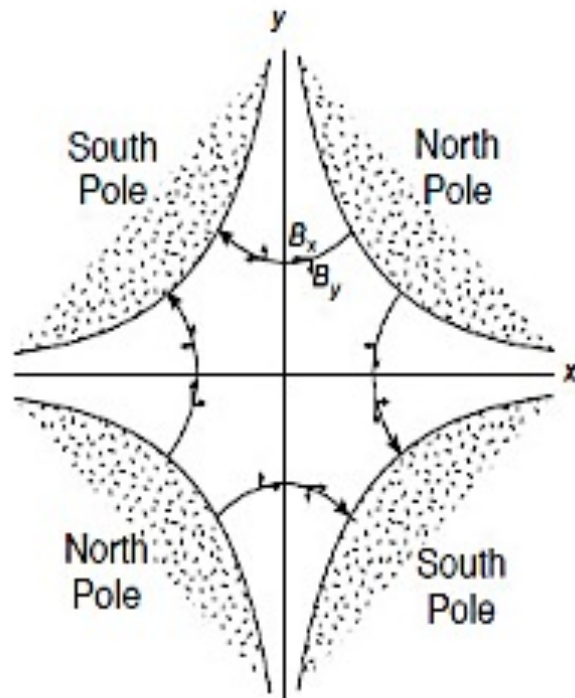

◆ Quadrupoles focus it

◆ Sextupoles correct chromaticity

Equation of motion in each coordinate

Magnetic field [T] : $B_y = \frac{\partial B_y}{\partial x} \times x$

Field gradient [T m⁻¹] : $g = \frac{\partial B_y}{\partial x}$

Normalized grad. [m⁻²] : $K = \frac{g}{p_0/e} = \frac{1}{f}$

$$x'' + K(s)x = 0$$

**Hill's
equation**

$K(s)$ describes the distribution of focusing strength along the lattice.

Alternating Gradient focusing → pseudo-harmonic oscillator with s -dependent spring constant $K(s)$.

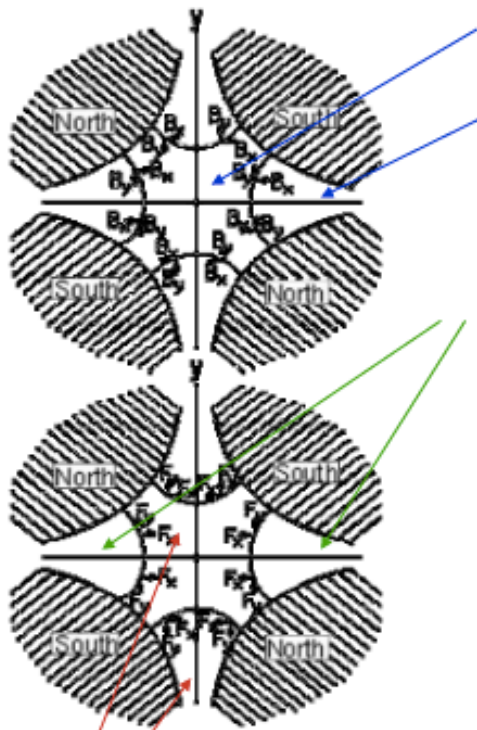

The general linear magnet lattice can be parameterized by a 'varying spring constant', $K=K(s)$

Note that dipoles give a "weak focusing" term in the horizontal plane, $K(s) = K(s) + 1/\rho^2$

Transverse focusing

Fields and force in a quadrupole

Focuses in horizontal plane

(hence is linear)

Force restores

Gradient $\rightarrow \frac{\partial B_y}{\partial x}$

Normalized:

$$k = -\frac{1}{(B\rho)} \cdot \frac{\partial B_y}{\partial x}$$

POWER OF LENS

$$\ell k = -\frac{\ell}{(B\rho)} \cdot \frac{\partial B_y}{\partial x} = \frac{1}{f}$$

Defocuses in vertical plane

Equation of motion in transverse coordinates

◆ Hill's equation (linear-periodic coefficients)

$$\frac{d^2 y}{ds^2} + k(s)y = 0$$

where $k = -\frac{1}{(B\rho)} \frac{dB_z}{dx}$ at quadrupoles

like restoring constant in harmonic motion

◆ Solution (e.g. Horizontal plane)

$$y = \sqrt{\beta(s)} \sqrt{\varepsilon} \sin[\phi(s) + \phi_0]$$

◆ Condition

$$\phi = \int \frac{ds}{\beta(s)}$$

◆ Property of machine $\sqrt{\beta(s)}$

◆ Property of the particle (beam) ε

◆ Physical meaning (H or V planes)

Envelope $\sqrt{\varepsilon\beta(s)}$

Maximum excursions

$$\hat{y} = \sqrt{\varepsilon\beta(s)}$$

$$\hat{y}' = \sqrt{\varepsilon / \beta(s)}$$

Each quadrupole lens couples position and angle in each transverse direction

The most general representation of the matrix $M(s)$ with unit modulus is given by the Courant-Snyder parameterization.

$$M(s) = \begin{pmatrix} \cos \Phi + \alpha \sin \Phi & \beta \sin \Phi \\ -\gamma \sin \Phi & \cos \Phi - \alpha \sin \Phi \end{pmatrix} = I \cos \Phi + J \sin \Phi$$

$$I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad J = \begin{pmatrix} \alpha & \beta \\ -\gamma & -\alpha \end{pmatrix}, \quad J^2 = -I, \quad \text{or } \beta\gamma = 1 + \alpha^2$$

The ambiguity in the sign of \sin can be resolved by requiring β to be a positive definite number if $|\text{Trace}(M)| \leq 2$, and by requiring $\text{Im}(\sin \Phi) > 0$ if $|\text{Trace}(M)| > 2$. The definition of the phase factor is still ambiguous up to an integral multiple of 2π . This ambiguity will be resolved when the matrix is tracked along the accelerator elements. Using the property of matrix J , we obtain the De Moivre's theorem:

$$M^k = (I \cos \Phi + J \sin \Phi)^k = I \cos k\Phi + J \sin k\Phi,$$

$$M^{-1} = I \cos \Phi - J \sin \Phi.$$

Drift section or dipole magnet:

$$M = \begin{pmatrix} 1 & L \\ 0 & 1 \end{pmatrix}$$

Focusing quadrupole:

$$M = \begin{pmatrix} 1 & 0 \\ \frac{1}{f} & 1 \end{pmatrix}$$

Example: FODO cell

A FODO cell is a basic block in beam transport, where the transfer matrices for dipoles (B) can be approximated by drift spaces, and QF and QD are the focusing and defocusing quadrupoles.

$$M = \begin{pmatrix} 1 & 0 \\ -\frac{1}{2f} & 1 \end{pmatrix} \begin{pmatrix} 1 & L_1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ \frac{1}{f} & 1 \end{pmatrix} \begin{pmatrix} 1 & L_1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\frac{1}{2f} & 1 \end{pmatrix}$$

$$= \begin{pmatrix} 1 - \frac{L_1^2}{2f^2} & 2L_1(1 + \frac{L_1}{2f}) \\ -\frac{L_1}{2f^2}(1 - \frac{L_1}{2f}) & 1 - \frac{L_1^2}{2f^2} \end{pmatrix}$$

$$M(s) = \begin{pmatrix} \cos \Phi + \alpha \sin \Phi & \beta \sin \Phi \\ -\gamma \sin \Phi & \cos \Phi - \alpha \sin \Phi \end{pmatrix}$$

$$\cos \Phi = \frac{1}{2} \text{Tr}(M)$$

$$\cos \Phi = 1 - \frac{L_1^2}{2f^2}, \quad \sin \frac{\Phi}{2} = \frac{L_1}{2f}$$

$$\beta = \frac{2L_1(1 + \frac{L_1}{2f})}{\sin \Phi} = \frac{2L_1(1 + \sin \frac{\Phi}{2})}{\sin \Phi}$$

$$\alpha = 0$$

This description works just as well for a linac as for a synchrotron or storage ring – main difference is that chromaticity and dispersion play an important role for circular machines.

Betatron phase space at various points in a lattice

Beam sections

I will present this as a personal tour through colliders I have known.

I began my career (I was once your age!) as a scientist on an experiment at CERN's [Intersecting Storage Rings \(ISR\)](#).

The ISR made p-p collisions up to 60 GeV collision energy, luminosity to $10^{30} \text{ cm}^{-2}\text{s}^{-1}$

The ISR did not produce a single important HEP discovery, but it ushered in several pivotal developments of accelerator physics and technology:

The ISR used momentum stacking to accumulate ~ 100 fills from PS – 20 A circulating d.c. current @ 30 GeV.

It required ultra-high vacuum for \sim week-long lifetimes.

Benvenuti invented

- getter pumping, later NEG
- plasma discharge cleaning for UHV

The crowning glory from ISR was stochastic cooling

FIG. 2. Cooling of the horizontal betatron oscillation of a single particle.

FIG. 3. Variation with system gain of the coherent cooling and incoherent heating effect.

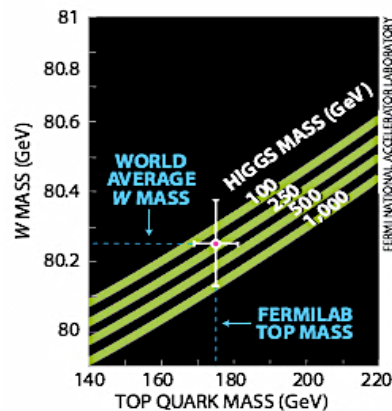

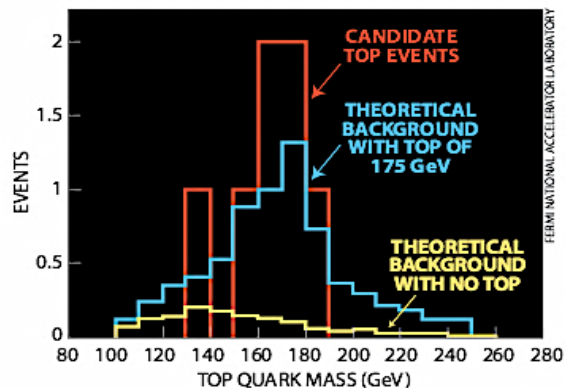

Simon van der Meer

Invented stochastic cooling to cool protons in the ISR

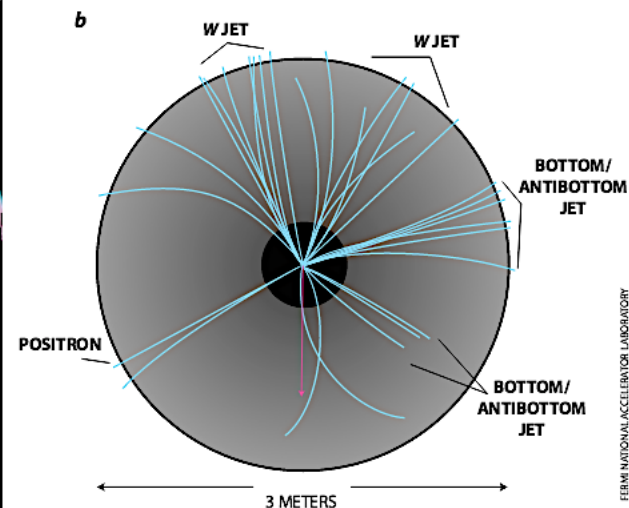

Used it to cool 5×10^{10} /hr antiprotons to discover the weak bosons in the $Spp\bar{S}$

The Tevatron: Anchor for a generation of HEP discoveries

One can still obtain a mass bump from a new particle, even at 175 GeV/c² mass!

The top quark and the Higgs are intimately related through gauge couplings: $-a_{scalar} \sim m_f$

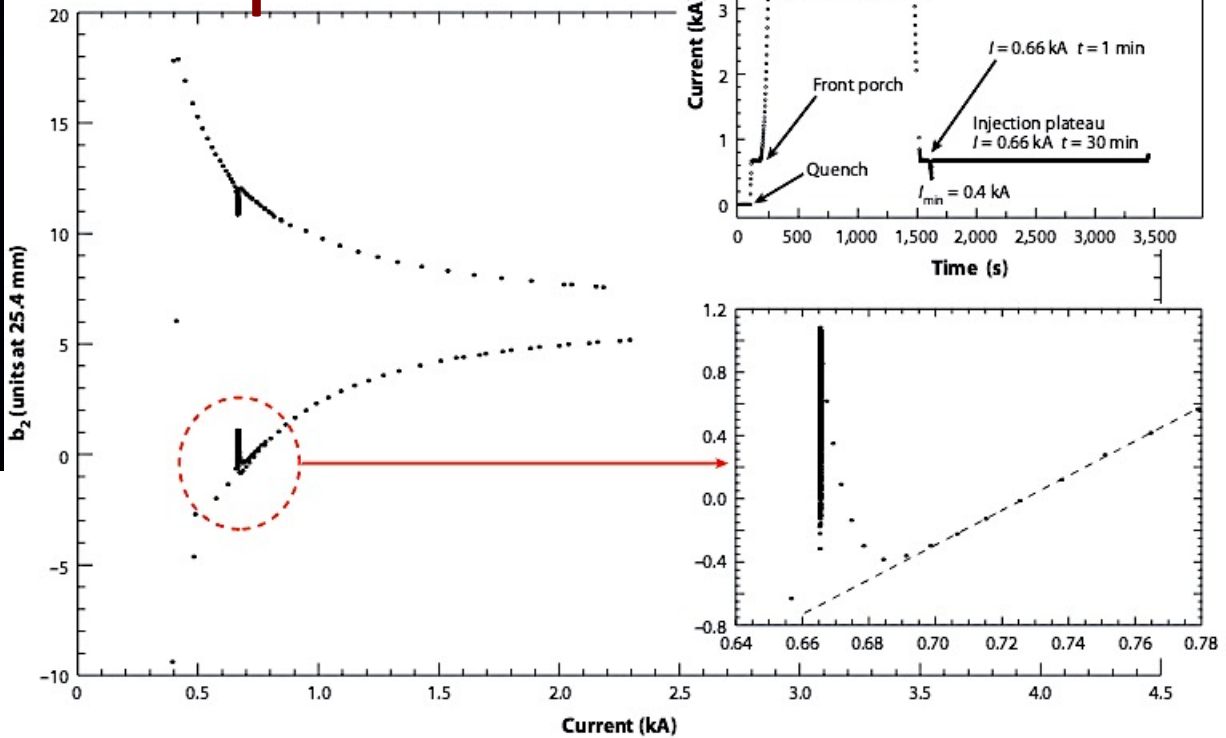

Tevatron the first-ever superconducting storage ring

Persistent current multipoles and snap-back

snap-back

One significant challenge for superconducting colliders is **snap-back**. When the dipole is ramped down to injection field, the superconducting currents within each filament are set on the discharging side of hysteresis loop.

When new beam is injected and the up-ramp begins, the currents re-distribute to the charging side: **snap-back**.

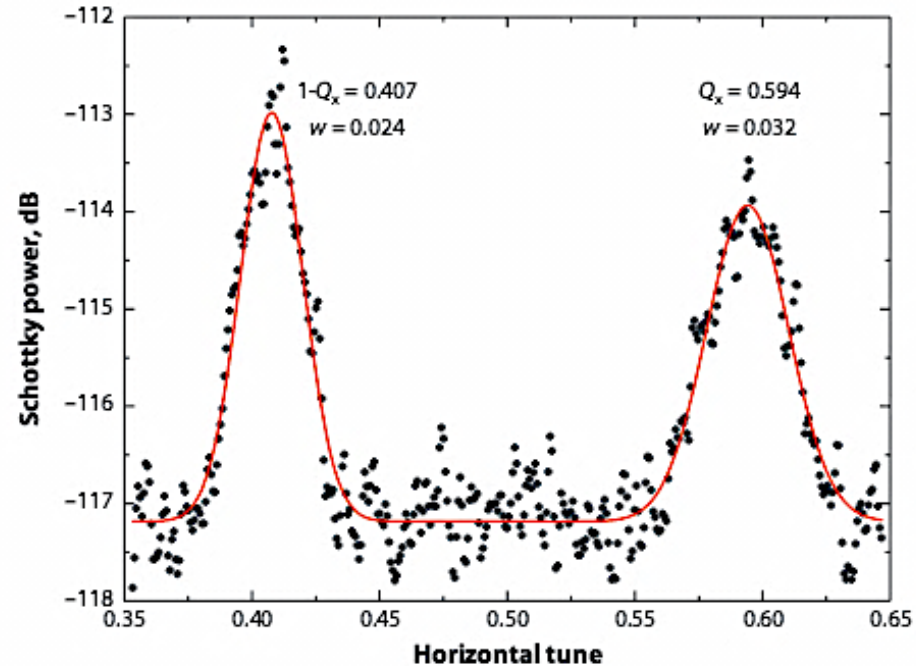

The sextupole component creates an instantaneous change in chromaticity that can be enough to blow the beam out of orbit.

Beam-beam tune shift

Red and green lines are sum and difference resonances up to 12th order.
Yellow dots are tunes of proton bunches. Blue dots are tunes of antiproton bunches.

Schottky scans in the Tevatron

As a proton passes through a slot-gap electrode, it induces a potential across the electrode that is proportional to its displacement from the axis.

The particles of each bunch induce a noise frequency spectrum that is proportional to \sqrt{N} . The protons are also undergoing betatron oscillations, so the Schottky spectrum is modulated to form sidebands.

A 1.7 GHz Schottky pickup was used to measure the betatron tunes of each individual bunch every day. The measurements were used to correct the tunes to keep maintain optimal working point.

Intrabeam scattering

The longitudinal and transverse emittances of each bunch are equivalent to [temperatures](#) in the frame of the bunch. The bunch is a gas with non-equilibrium temperatures.

$T_{\perp} \ll T_{\parallel}$ as a natural consequence of acceleration (homework).

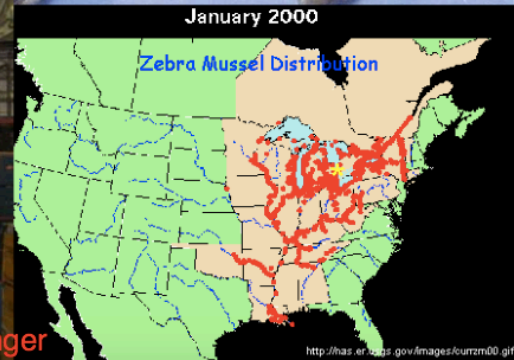

In the bunch frame, the particles Coulomb scatter, and the scattering is heat transfer from the hot dimension to the cold dimension.

Challenges for collider operation

Coalescing antiproton bunches in the Main Injector for transfer to Tevatron

Beam Beam Tune Shift

The luminosity of collisions and the beam-beam tune shift have the same dependences on the beam emittance:

$$L = \frac{N^2 f}{4\pi\sigma_x\sigma_y}$$

$$\xi = \frac{Nr_p}{4\pi\epsilon_n}$$

$$L = \frac{\gamma\xi Nf}{\beta_x r_p}$$

Simple example: round Gaussian beams

- Assumption 1: $\sigma_x = \sigma_y = \sigma$, $Z_1 = -Z_2 = 1$
- Assumption 2: very relativistic $\rightarrow \beta \approx 1$
- Only components E_r and B_ϕ are non-zero
- Force has only radial component, i.e. depends only on distance r from bunch centre (where: $r^2 = x^2 + y^2$) (see proceedings)

$$F_r(r) = -\frac{Ne^2(1+\beta^2)}{2\pi\epsilon_0 \cdot r} \left[1 - \exp\left(-\frac{r^2}{2\sigma^2}\right) \right]$$

LEP - LHC

	LEP (e ⁺ e ⁻)	LHC (pp)
Beam sizes	160 - 200μm · 2 - 4μm	16.6μm · 16.6μm
Intensity N	4.0 · 10 ¹¹ /bunch	1.15 · 10 ¹¹ /bunch
Energy	100 GeV	7000 GeV
$\epsilon_x \cdot \epsilon_y$	(≈) 20 nm · 0.2 nm	0.5 nm · 0.5 nm
$\beta_x^* \cdot \beta_y^*$	(≈) 1.25 m · 0.05 m	0.55 m · 0.55 m
Crossing angle	0.0	285 μrad
Beam-beam parameter(ξ)	0.0700	0.0037

Beam-beam kick:

Kick ($\Delta r'$): angle by which the particle is deflected during the passage

Integration of force over the collision, i.e. time of passage Δt (assuming: $m_1=m_2$ and $Z_1=-Z_2=1$):

$$\text{Newton's law: } \Delta r' = \frac{1}{mc\beta\gamma} \int_{-\frac{\Delta t}{2}}^{+\frac{\Delta t}{2}} F_r(r, s, t) dt$$

with:

$$F_r(r, s, t) = -\frac{Ne^2(1+\beta^2)}{\sqrt{(2\pi)^3}\epsilon_0 r\sigma_s} \left[1 - \exp\left(-\frac{r^2}{2\sigma^2}\right) \right] \cdot \left[\exp\left(-\frac{(s+vt)^2}{2\sigma_s^2}\right) \right]$$

- For small amplitude: tune shift
- For large amplitude: amplitude dependent tune shift

Beam-beam force/kick

There is a fundamental difference in the significance of beam-beam tune shift for an e⁺e⁻ collider and a hadron collider:

The electron emittance is damped by synchrotron damping. Each electron in LEP 'forgets' what harm was done to it on the last orbit.

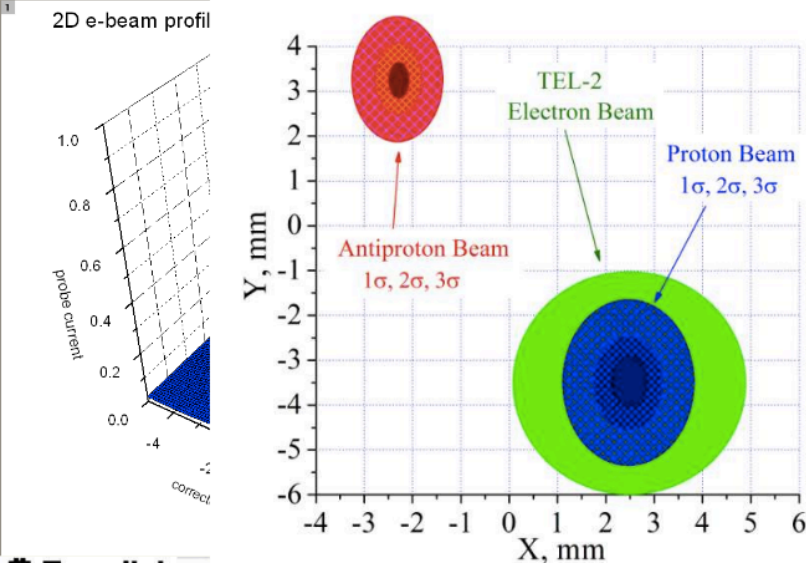

But the protons in LHC have very little synchrotron damping. They remember all the harm done, on all the orbits, for a day! Comparable to the Earth's orbits in its history...

Electron Lens was used on Tevatron for two purposes:

1. Gaussian-profile e-beam compensates beam-beam tune shift:

in Tevatron operation - TELs compensated of long range BB effects

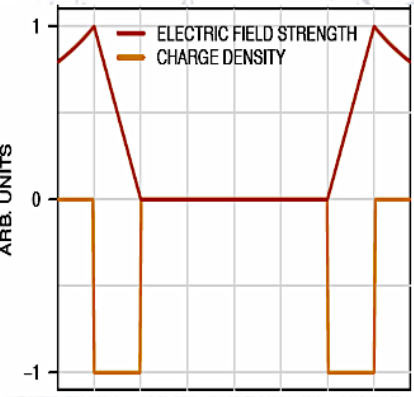

TEL2 on One "Bad" Bunch (P12)

2. Hollow e-beam, notched on during gap, removes d.c. beam

**No EM field inside
Strong field outside**

Tevatron HEB-Collimator

To explore advantages:

- ▶ Kicks are small but not random
- ▶ Halo diffusion enhancement ("smooth" scraper)
- ▶ Resonant excitation is possible (pulsed e-beam)
- ▶ No material damage
- ▶ No ion breakup
- ▶ Low impedance
- ▶ Position control by magnetic field (no motors or bellows)
- ▶ Established e-lens technology

LHC Collimators

Task: absorb halo proton and neutrons straying around the beam

movable jaws (with RF shield)

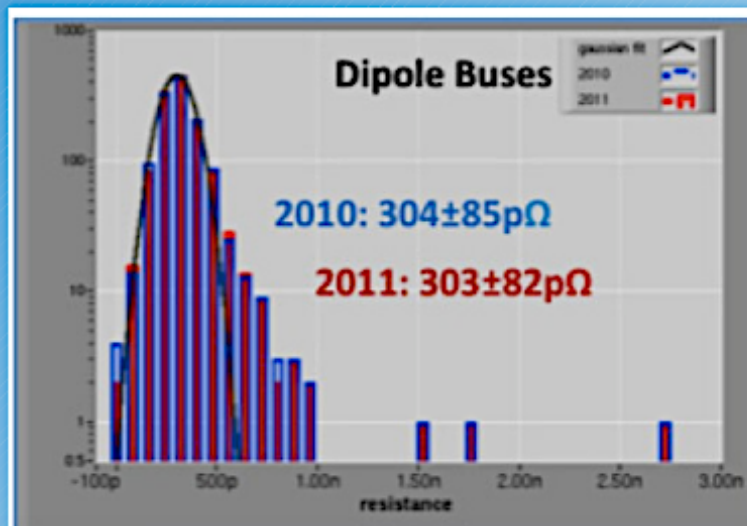

And then...

All superconducting magnets in LHC connect their supply and return currents through **current bus cables**, located in conduits within the magnet cryostats. Each bus in each magnet must be spliced to the same bus in the neighboring magnets. Those splice joints must be stable against quench. The provisions for stabilizing copper, and the provisions for soldering, were inadequate in the original installation.

Interconnection Joints

Splice Resistance Measurements (A.Siemko et al)

LHC Repair

Quench protection of the superconducting magnets

LHC dipole protection: practical implementation

It's difficult! - the main challenges are:

1) Series connection of many magnets

- In each octant, 154 dipoles are connected in series. If one magnet quenches, the combined energy of the others will be dumped in that magnet \Rightarrow vaporization!
- **Solution 1:** cold diodes across the terminals of each magnet. Diodes normally block \Rightarrow magnets track accurately. If a magnet quenches, it's diodes conduct \Rightarrow octant current by-passes.
- **Solution 2:** open a circuit breaker onto a resistor (several tonnes) so that octant energy is dumped in \sim 100 secs.

2) High current density, high stored energy and long length

- Individual magnets may burn out even when quenching alone.
- **Solution 3:** Quench heaters on top and bottom halves of every magnet.

But the quench heater leads are beginning to fail open.

It is suspected that warmup-cooldown stresses weaken the connections.

LHC quench-back heaters

- stainless steel foil 15mm x 25 μ m glued to outer surface of winding
- insulated by Kapton
- pulsed by capacitor 2 x 3.3 mF at 400 V = 500 J
- quench delay - at rated current = 30msec
- at 60% of rated current = 50msec
- copper plated 'stripes' to reduce resistance

CERN is evaluating a new quench protection method: CLIQ

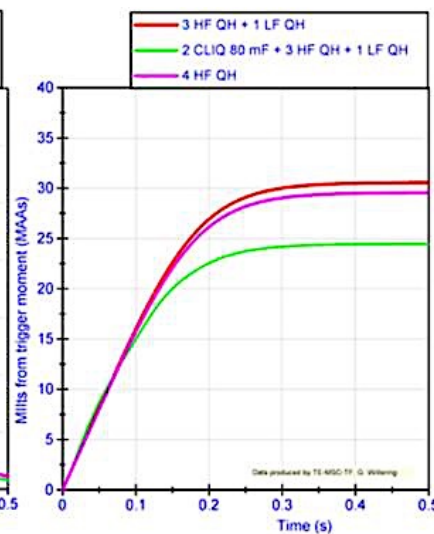

Datskov, GSI

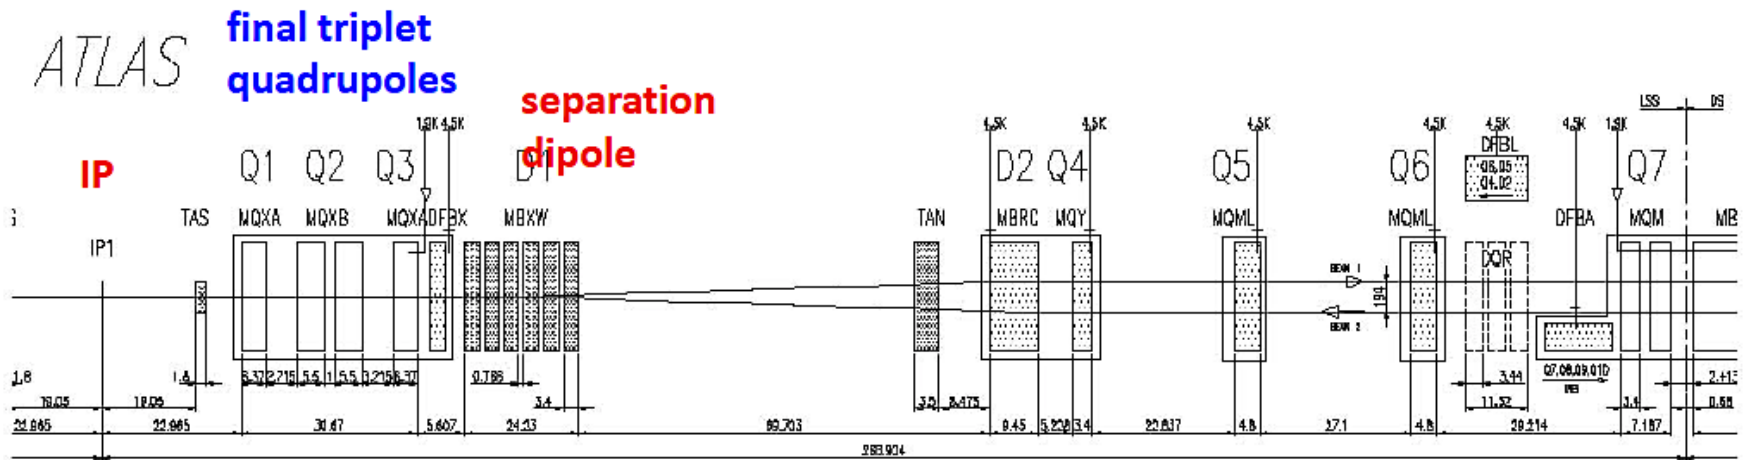

Discharge a capacitor across the inductive circuit of the dipole winding.

It induces distributed AC loss spike that drives quench everywhere in winding.

It works great on an LHC dipole:

LHC interaction-region layout

nominal bunch spacing = 7.5 m
 nominal collision spacing = 3.75 m
 → about 2x15 collisions between
 IP and separation dipole!
 tune shift would increase 30 times!
 solution: crossing angle

Electron cloud: δ_{\max} in the arcs: results

LHC – longitudinal instability

main cure: controlled longitudinal blow up on LHC ramp

feedback on bunch length measurement modulates noise amplitude to control blow-up rate; bunch lengths converge correctly to target 1.5 ns (now ~1.25 ns)

Back in business...

Discover the Higgs...

Then what?

- Supersymmetry
 - Naturalness bound...

The Standard Model

- It's an effective theory with many unanswered questions

- What determines the masses?
 - particularly the 3rd generation?
- Why this energy scale?
 - Electroweak scale $\sim 0.1-1.0$ TeV
 - The only 'natural' scale is the Planck scale ($\sim 10^{19}$ GeV)
 - $m_H = 125$ GeV requires extraordinary fine tuning of SM parameters

Prime candidate (is still) Supersymmetry

- SUSY provides appealing Dark Matter candidates
 - Light Supersymmetric Particles – e.g. Neutralino (or Gravitino...)
- Provides remarkable unification of forces
 - At the grand unification scale $\sim 10^{16}$ GeV

- Predicts a standard-model-like Higgs with $m_h < 130$ GeV!

Report card from CMS

Summary of CMS SUSY Results* in SMS framework

*Observed limits, theory uncertainties not included

Only a selection of available mass limits

Probe *up to* the quoted mass limit

The pileup challenge

Events taken at random
(filled) bunch crossings

2010

O(2) Pile-up events

150 ns bunch spacing

2011

O(5-10) Pile-up events

50-75 ns bunch spacing

2012

O(20-30) Pile-up events

50 ns bunch spacing

Pileup beyond design value

- Runs 2 and 3: O(50-60) PU
⇒ Phase 1 upgrades
- At HL-LHC PU O(140-200)
⇒ Phase 2 upgrades

Luminosity upgrades

forecast to 2021 (25 & 50 ns)
from Frank Zimmermann (CERN)

- pile up high (80-120) in 2015-2017 with 50 ns spacing (50-ns pile up >2x more than for 25 ns spacing)

luminosity leveling at the HL-LHC

example: maximum pile up 140

Nb₃Sn Superconducting Magnets for the Luminosity Upgrade

Fig. 2. RRP108/127 and RRP150/169 strands and 40-strand cored cable.

11 T dipoles to free space for dispersion suppressors in the arc lattice.

Fig. 3. Impregnated coil (left) and coil cross-section (right).

Fig. 4. Stainless steel collars (left) and collared coil assembly (right).

200 T/m quadrupoles with 120 mm aperture for the low-beta triplets flanking each IP.
